ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY

President THE MOST HON THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders persons suffering from incipient nervous and mental disorders as well as certified patients of both sexes are received for treatment. Careful clinical biochemical bacteriological, and pathological examinations. Private rooms with special nurses male or female in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds with a separate entrance to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods including Turkish and Russian baths the prolonged immersion bath Vichy Douche Scotch Douche Electrical bath Plombieres treatment etc. There is an Operating Theatre, a Dental Surgery an X-ray Room an Ultra-violet Apparatus and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical bacteriological and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk meat fruit and vegetables are supplied to the Hospital from the farm, gardens and orchards of Moulton Park. Occupation therapy is a feature of this branch and patients are given every facility for occupying themselves in farming gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan amidst the finest scenery in North Wales. On the North West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts) croquet grounds, golf courses and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton) who can be seen in London by appointment.

Appointment of a Registered MEDICAL MAN OR WOMAN AS A RESEARCH WORKER IN MENTAL DEFICIENCY

READVERTISED AT AN INCREASED SALARY

The MEDICAL RESEARCH COUNCIL, the GOVERNING BODY OF THE DARWIN TRUST and the COMMITTEE OF THE ROYAL EASTERN COUNTIES INSTITUTION for the MENTALLY DEFECTIVE at COLCHESTER, jointly invite applications from registered Medical Men or Women to undertake research into Mental Deficiency.

The person appointed will be a member of the Medical Staff of the Royal Eastern Counties Institution and will be expected to take some part in the Administrative and Clinical work of the Institution itself but the major part of the work will be an investigation into the causes of mental deficiency from the clinical, social, and genetic aspects. A Social Investigator will be appointed to assist in the work.

Commencing salary at the rate of £ 500 a year, non-resident.

A form of application can be obtained from the Medical Superintendent, Royal Eastern Counties Institution, Colchester, which must be completed and returned before October 4th. Duties to commence January 1st 1931.

Shanghai Municipal Council

PUBLIC HEALTH DEPARTMENT

SECOND ASSISTANT COMMISSIONER OF PUBLIC HEALTH (HOSPITALS)

A Second Assistant Commissioner of Public Health (Hospitals) is required in the Public Health Department of the Shanghai Municipal Council.

Candidates preferably unmarried, should not be more than 30 years of age and must hold qualification in Medicine and Surgery of Unit Medical standard a D.P.H. though not essential is desirable. Candidates must have held resident Hospital appointments, medical and surgical and practical experience of Isolation Hospital, V.D. and T.B. service is desirable.

Salary Taels 630 per mensem or Taels 700 per mensem if holding a D.P.H. during three years agreement.

The agreement is renewable in the event of satisfactory services at a triennial increase of Taels 100 per mensem up to Taels 1,000 or Taels 1,050 per mensem if holding a D.P.H.

A Tael at the present rate of exchange equals about 1/7d. Exchange is however subject to fluctuation.

A temporary bonus of Taels 75 per mensem is granted at the present time to compensate for the increased cost of living and under certain limitations a guarantee of one-third of pay and bonus will be paid at the equivalent of 2/6 to the Tael to offset the adverse fluctuations in the rate of exchange.

The Assistant Commissioner of Public Health (Hospitals) provided he holds the D.P.H. is eligible for the higher appointments of Deputy Commissioner of Public Health and Commissioner of Public Health the present maximum pay for which is Taels 1,350 and Taels 2,000 per mensem respectively.

First-class passage is given with half pay during voyage.

Eight months' leave is given on full pay with first-class passage, after every period of five years service in Shanghai.

Free medical attendance is provided, and there is participation in the benefits of a Superannuation Fund.

Particulars of the appointment, and full details as to the benefits enjoyed by Municipal employees under their Terms of Service may be obtained from the Council's Agents.

Applications in candidates own handwriting with full information as to their qualifications, experience etc., accompanied by at least three recent testimonials and endorsed "Second Assistant Commissioner (Hospitals)" on the cover should be forwarded to Messrs. JOHN POOK & CO., Agents for the Municipal Council of Shanghai, 63, Fenchurch Street, London, E.C.3.

September 1930.

County Borough of Wigan

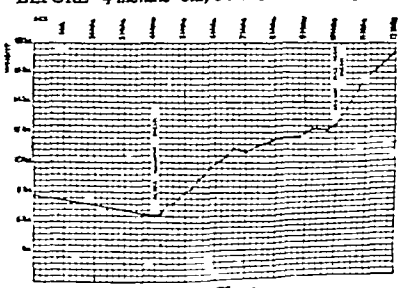
A "RESURRECTION"

GUILDFORD
30 6/30



"Baby Hook, came under my care shortly after birth suffering with marasmus following whooping cough Broncho-pneumonia developed and was with great difficulty cleared up, leaving the child in a very low condition Feeding proved a difficult problem, several things were tried without beneficial results The results with Cow & Gate were truly wonderful, indeed it is a case of 'a resurrection.'"

(Signed) M.B Ch B

Lacidac (separated) and Brestol, the Cow & Gate Humanised Cream, were used in the early days of treatment. Cow & Gate Full Cream and Brestol being used subsequently.

BEFORE—4 months' old, 6 lbs. 9 ozs. in weight.

Progress Chart

AFTER—10 months' old, 12 lbs. 6 ozs. in weight.

June 1930 Baby Hook has now won a prize in a Baby Competition!

Write for literature and clinical samples of Lacidac and Brestol.

ISSUED WEEKLY] [COPYRIGHT] [REGISTERED AS A NEWSPAPER

THE RATIONALE OF THE ACTION OF RYVITA CRISPBREAD IN CERTAIN SPECIAL CONDITIONS

OBESITY AND MALNUTRITION

These conditions are here treated together because they are both due to faulty metabolism In both conditions there is some interference with the process either of digestion, of absorption, or of assimilation Ryvita is a food which is eminently easy of digestion in the first place, and also of absorption, and of assimilation Ryvita, therefore, is body-building, not fat forming

Ryvita's natural laxative action, also, keeps the body in perfect condition

It may be noted here, also that recent investigation has shown that there is considerable evidence that Vitamin B plays a considerable part in carbohydrate metabolism

Ryvita is made of pure crushed wholegrain rye It is balanced by its own B Vitamin, since the structure of rye grain prevents the germ being lost in the milling, as it so often is from wheat or oats Ryvita is rich in the natural organic salts of iron phosphorus and lime

Ryvita is definitely indicated as an item of the dietary in treatment of disorders arising *from digestion, constipation,* or malnutrition It is usual to suggest that the patient begin by eating two or three slices of Ryvita with at least one meal each day

RYVITA

CRISPBREAD

We shall be very pleased to send Free Samples and full particulars to any interested Member of the Profession.

REBUILDING.

During the erection of the New Premises on the site of 136, Gower Street and 24, Gower Place, **business i** being **carried on as usual** in the completed portion of the new building on the site of 134, Gower Street. *(Entrance adjoining the Architecture Department of University College.)*

The **BOOKSELLING DEPARTMENT—Medical** (Ground Floor), **Scientific and Technical** (First Floor), and **Stationery Department** (Downstairs) are accommodated as stated until the whole building is completed

The **CIRCULATING LIBRARY** is permanently moved to this portion, increased accommodation being provided both in the **Exchange Department** (Ground Floor) and the **Reading Room** (First Floor)

The Postal Address and Telephone Numbers are unchanged

The completed building, extending from the College in Gower Street round the corner of Gower Place, will be uniform in architectural design, and is being erected by Messrs H K Lewis & Co Ltd Under an agreement with the London University, the Company have made some sacrifice of space on their own site to meet the necessities of the design in return for certain concessions from the University as to the site of No 134.

The Department for Secondhand Books
remains at 140 Gower Street Telephone Museum 4031.
The Publishing and Wholesale Office
is unaltered 28 Gower Place Telephone Museum 2853

CANCER of the LUNG AND OTHER INTRATHORACIC TUMOURS
By MAURICE DAVIDSON, M A , M D ,
B Ch (Oxon) F R C P (Lond),
Physician to the Brompton Hospital for Consumption and Diseases of the Chest and Dean of the Brompton Hospital Medical School etc

FROM THE FOREWORD BY
ARTHUR J HALL M A M D D Sc., F R C P
Professor of Medicine in the University of Sheffield

If the practitioner is aware of the varied and insidious disguises which early pulmonary cancer may assume and if he knows what steps must be taken to unmask them it rests with him by action upon such knowledge to help more than anyone else in forwarding advance in the treatment of this grave disorder

Bristol JOHN WRIGHT & SONS Ltd [Illustrated Catalogue free] London SIMPKIN MARSHALL Ltd.

DISEASES OF THE HEART THEIR DIAGNOSIS, PROGNOSIS, AND TREATMENT BY MODERN METHODS.

With chapters on the Ink Polygraph, Clinical Electro-Cardiography, X-Ray Examination, and Anæsthesia in Relation to Cardio-Vascular Affections

By FREDERICK W PRICE, M D , F R S (Edin),

Senior Physician to the National Hospital for Diseases of the Heart Consulting Physician to the Royal Northern Hospital London
Demy 8vo Pp 634 With 249 text figures including 32 sphygmograms 92 polygraphic tracings and 87 electro-cardiograms
NEW SECOND EDITION, 21s net

By great care and by the use of an amazing amount of material he has accomplished what many readers have been waiting for, giving us a complete account of the diagnosis prognosis and treatment of heart diseases by modern methods in association with all the invaluable teaching bequeathed to us by the older masters of clinical observations —LANCET
The most valuable and comprehensive guide to the study of Cardiology with which we are acquainted '—NEW YORK MEDICAL JOURNAL AND RECORD
We think that most of our readers engaged in general practice will find this work extremely useful '—THE JOURNAL OF CLINICAL RESEARCH
In our opinion the book is indisputably the most authoritative contribution to cardiology of our time —PANAMA MEDICAL REVIEW
A book which we believe is destined to remain the standard work on Cardiology for many years to come —AMERICAN MEDICINE

The second edition of this popular work on heart disease bears evidence of thorough revision, while the essentially clinical standpoint of the writer is maintained '—EDINBURGH MEDICAL JOURNAL
'It may be said at once that the book adequately fulfils the purpose it has in view and is a perfectly sound, lucid and reliable guide —NEWCASTLE MEDICAL JOURNAL
Well written, concise and complete containing a wealth of practical information Obviously based upon the author's own experience and investigative work —SURGERY GYNECOLOGY, AND OBSTETRICS (Official Journal of the American College of Surgeons)
Dr Price is to be congratulated again on the reappearance in its second edition of his distinguished contribution to the increasingly important subject of Cardiology —THE CANADIAN JOURNAL OF MEDICINE AND SURGERY

MICKLEFIELD IRRADIATED MILK

TREATING THE MILK

By this Process—

(1) VITAMIN A AND NATURAL FLAVOUR ARE PRESERVED

(2) VITAMIN D CONTENT IS INCREASED 1,800 PER CENT, OR TEN TIMES THAT OF ANY OTHER IRRADIATED MILK.

One pint equivalent in Vitamin D to 600 drops or 12 grammes of average Cod-Liver Oil

A ten weeks test recently conducted at the Infants School Rickmansworth, under the supervision of the Medical Officer of Health, gave the following results :—

(1) 18 children (controls) had their usual ordinary milk
(2) 29 1/3 pint of Grade A (T T) milk five days a week
(3) 30 Micklefield " "

(1) Average increase in height 605 in (2) Average increase in weight 9 72 ozs more than (1)
(2) 610 in (3) " 10 9 ozs more than (1)
(3) 744 in

Full particulars appeared in an article in the LANCET, January 18, 1930, p 127, et seq, a reprint of which will be sent post free on request

The milk is delivered every week-day in London, elsewhere by arrangement.

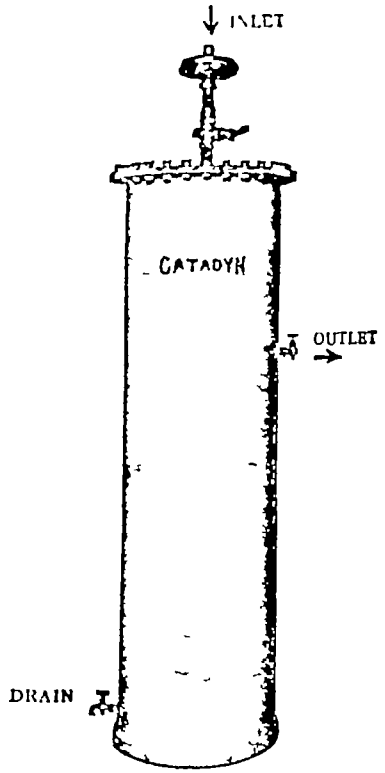
DOWN BROS. LTD. - LONDON

The simplest known method of making drinking water safe

No chemicals – no trouble – no risk

In all parts of the world there are thousands of people compelled to draw their water supplies from suspected sources Catadyn is an entirely new method of dealing with this problem Hitherto no method has been entirely satisfactory—the addition of chemicals, the close supervision, the change of colour or taste, being only some of the many disadvantages of other systems But with Catadyn it is different Here are some of its unique advantages



1 The colour, taste and smell of the water are in no way affected

2 There are no chemicals to add, and thus no risk of overdosage

3 The action is largely catalytic, so that only one litre of Catadyn sterilising elements will deal with hundreds of thousands of gallons

4 The water treated by Catadyn becomes bactericidal and has been shown to remain bactericidal as long as 14 months after treatment

Every one of these claims can be supported by tests carried out by the highest authorities in all countries in the world Full copies of these tests are available for all members of the medical profession

The above Catadyn steriliser is suitable for a fairly large domestic and hospital supply With water containing as many as 36,000 B coli per 100 cc, this plant will pass out 22 gallons per hour of germ-free water There are other smaller types suitable for dealing with small quantities

The British Catadyn Company desire to secure the investigation of this remarkable invention by the Medical Profession and are prepared to send a small steriliser for test purposes upon request to the address below

ETHYL CHLORIDE B.D.H.

Issued for general and for local anaesthesia the container in each case being fitted with a special spray nozzle

For General and Local Anaesthesia

Ethyl Chloride has been described as

> "one of the safest of all anaesthetics, not even excepting nitrous oxide and oxygen."
> —*B.M.J. 1929 I 500*

As with all anaesthetics however the safety of ethyl chloride depends largely upon its degree of purity

Ethyl Chloride B.D.H. is a British made product of a higher standard of purity than that required by the British Pharmacopoeia. Ethyl Chloride B.D.H. is rapid in action and its administration produces no unpleasant after-effects it is particularly useful in minor operations requiring a general anaesthesia lasting for 1 to 5 minutes, also in major operations as a preliminary induction to ether

The use of Ethyl Chloride B.D.H. as a reliable local anaesthetic is sufficiently well known.

Clinical sample on request

STANIFORM

Regd. BRAND Trade Mark.

METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns scalds etc

DUSTING POWDER
For application where a greasy substance is counter indicated

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis

LOTION
A panacea for Mosquito and other insect bites Most effective for all purposes where Tr Iodine is employed. Does not stain the skin and there is no sting

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use

Supplies may be obtained through the Wholesale Druggists Druggist Sundriesmen or Dental Supply Companies

What the Profession says

The following are some recent unsolicited testimonials reported to the Manufacturers by Medical Men

"I continue to get every satisfaction from Staniform in the case of carbuncles boils whitlows and all kinds of infected wounds."

"In a case of acute eczema on leg the skin was quite normal within one week after starting application of Staniform Ointment."

Festering wound on left heel when first seen was about the size of a shilling with good deal of pus. Four days after much swollen—dressed with Staniform Ointment healed splendidly in four days."

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns Wounds and Skin Ailments

STANIFORM is used in Leading Hospitals.

STANIFORM owes a wide field of clinical experience has exhibited positive curative properties in combining the well known virtues of Tin in staphylococcic infections with the powerful germicidal properties of Iodine Staniform is indicated generally in local inflammations inducing an immediate soothing effect with rapid healing

HARDEN BROS & LINDSAY LTD
(Dept 153) 30/34 Mincing Lane London E.C.3

ALLERGIC CONDITIONS AND PROTEIN SENSITISATION

MUCH attention has of late been directed to states in which the subject has become sensitised to some substance, and on exposure to the same substance reacts in a characteristic manner

The substances which may sensitise are very varied (e g, animal dandruff and hairs, plant pollens and hairs, animal and vegetable proteins of foods, bacteria and their products) and the reaction may take the form of epileptic attacks, fainting fits, skin eruptions, asthma, e tc

In many instances the sensitisation is produced by bacteria or their products in the bowel, and by the exhibition of an efficient intestinal disinfectant the subject is cured This has been found to occur in many cases of asthma, eczema and, other skin diseases

The best of all intestinal disinfectants is Kerol, which acts as a specific cure in many of these cases

For intestinal disinfection, use KEROL CAPSULES (keratin-coated), they contain 3 minims of Kerol One to three capsules may be given three or four times a day after meals

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl salicylic acid possesses a notable disadvantage Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced

"Alasil" completely overcomes this objection By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract "Alasil" is therefore a triumph over acetyl salicylic acid It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time Analgesic, Antipyretic and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore

A supply for clinical trial with full descriptive literature sent free on request

Infantile Diarrhoea.

A letter recently received

The Medical Adviser of Messrs Kaylene Ltd,
London

Dear Sir,

The case to which I referred was a child of six months who was brought to me after having treatment elsewhere for diarrhoea and vomiting The child was practically a skeleton and apparently had been vomiting everything—even medicines—for many days The mother thought and her friends thought, the child was dying, and I happened to be the nearest doctor I gave the child one teaspoonful of plain Kaylene in plain, cold, boiled water, and kept the mother and child in my consulting room to watch effects If ever a child was drawn from the jaws of death, I think that little sufferer was The Kaylene was retained, the gasping steadily lessened, the haunting look *of that child's eyes became less distressing, in fact the change for the better was so pronounced that in an hour's* time I allowed the mother to take the child home

Fortunately, I had sufficient Kaylene by me (a sample you kindly sent), and I gave the mother sufficient to give a teaspoonful every hour during the night The chemists shops were all shut by this time I gave full instructions—strict instructions—not to give anything else but Kaylene and plain, cold, boiled water as I had done

In the morning the mother came to see me and informed me that only twice during the night the child had loose stools but no vomiting, and had slept fairly well The child had other two loose motions during the day but not offensive ones like all the other stools In the evening the child cried—the first time for two days—and as she looked, and was, so much better, I gave her some white of egg with plain, cold boiled water Still improving, I kept her on this for three days She was doing well and I then allowed her milk She made a complete recovery, and there can be no doubt whatever that Kaylene saved the child's life

Yours faithfully,

, M B, C M

MEDULLA RUBRA

BONE-MARROW IN ANAEMIA FROM HAEMORRHAGE

W Borchardt (*Deut med Woch* March 28th, 1930 p 521) records the results of his experiments on young dogs in which anaemia had been artificially produced by the removal of about half their blood In the first series some of the animals were fed with rib marrow others with marrow from the long bones Control animals received a corresponding amount either of fat or of liver extract The basal diet in each case contained a sufficiency of iron (5 mg per cent) Only the animals receiving the red rib marrow showed a definite increase of weight, and their haemoglobin formation was more rapid than that of the others In the next series the experiment was repeated, but the iron content of the diet was reduced to 1 4 mg per cent The result was similar but more striking the dogs receiving the rib marrow regaining their haemoglobin far more quickly than the others.

THIS extract from the "Epitome of Literature," published in the "BRITISH MEDICAL JOURNAL," dated May 3rd last, is important as representing, in 1930, a complete justification of the formula upon which

Roboleine
THE FOOD THAT BUILDS THE BODY

has been produced without variation during the past twenty-five years

The success of ROBOLEINE is thus due to intelligent anticipation and to consistently maintaining the highest possible standard of manufacture.

Medical Practitioners are asked to satisfy themselves of the merits of ROBOLEINE, for which purpose testing samples will be gladly sent upon request.

Dimol

the Safe and Effective Intestinal Disinfectant

Before the discovery of Dimol the use of intestinal disinfectants was discredited owing to the impossibility of administering anything which was non-toxic to the host in the necessary dosage to produce the desired result

Dimol does not liberate phenol in its passage through the intestinal canal—it is not split up or absorbed, nor does it enter into combination with other drugs When it comes in contact with the pancreatic fluid it is emulsified and goes forward with the faeces and is voided unchanged.

The dose recommended for Dimol is 2 to 4 pulverettes—say 3 Each pulverette contains 1 gr Dimol, and Dimol is 35 times more efficient as a bactericide than Phenol that is to say, in administering 3 Dimol pulverettes the patient is receiving the bactericidal equivalent of 105 grains of Carbolic Acid

After long and careful investigation at the Royal Naval College, Greenwich, Dimol Pulverettes are now being issued by the Admiralty for use in His Majesty's Ships and Royal Naval Hospitals.

Vita-Weat contains every part of the wheat berry

When a diet regime is prescribed it is usual to include Vita-Weat, the British whole-wheat crispbread, in place of soft whole-meal or white bread.

Vita-Weat is an article of diet combining the nutritive and health-giving properties of the best wholemeal bread with the palatability of the white loaf, at the same time ensuring an easily digested product with a high Vitamin, Caloric and Protein content

It is an all-British crispbread, guaranteed to be made from 100 per cent stone-ground whole-wheat grown within the Empire It is of distinctive texture, inviting mastication and insalivation, it has a delicious "crunchiness" and a pleasing ripe-corn flavour, and it contains every part of the wheat berry, nothing whatever being removed in the process of manufacture

Not the least of the many benefits to be obtained from a regular diet of Vita-Weat is that of intestinal correction and the prevention of many of the intestinal and gastro-intestinal ailments due to constipation

When forming a suitable proportion of the daily diet, Vita-Weat acts as a stimulant to normal peristalsis, whilst not exerting an undue irritative effect on the intestinal mucous membrane

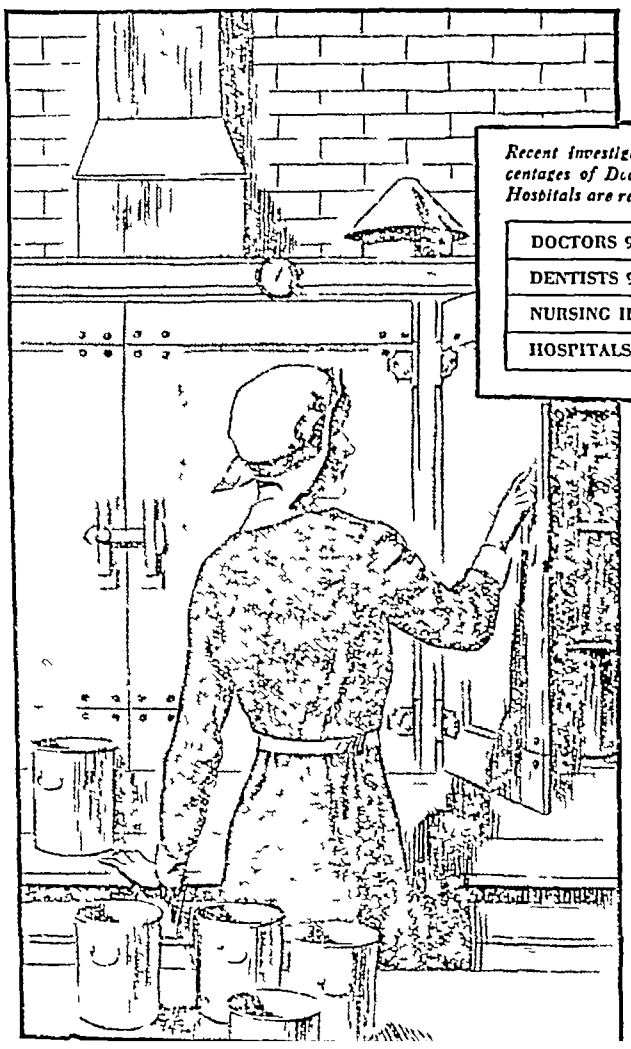
At that critical time when solid food cannot be taken—

THEY STIMULATE THE SYSTEM AND ROUSE THE APPETITE!

BY APPOINTMENT

Through this wonderful process — exclusive to Brand's — the pure essence of the finest meats is expressed and conserved in its natural form.



TODAY, in cases of serious illness and in convalescence, leading British practitioners find Brand's Essence an ideal restorative and stimulant A recent investigation shows that 99 *out of every* 100 doctors recommend this famous product.

Containing all those valuable elements of meat which excite the gastric secretions, Brand's Essences promote the flow of these secretions and rouse them to the work of digestion instantly

They are formed entirely of the pure essences of the finest meats, expressed and conserved in their natural state There is not a particle of harmful colouring, flavouring, or added gelatine in Brand's Essences

This delicious, palatable jelly can be absorbed rapidly, without the slightest strain on the digestive organs, however delicate their condition

In acute illness, Brand's Essences stimulate — carry the patient through the most trying periods And in convalescence, when ordinary food is intolerable, they awaken appetite and make the patient more responsive to solid diet

Recent investigation shows that the following percentages of Doctors Dentists Nursing Homes and Hospitals are recommending Brand's Essences

DOCTORS	99%
DENTISTS	92%
NURSING HOMES	78%
HOSPITALS	61%

They are obtainable at chemists and stores throughout the world in small and large-sized tins and glasses On receipt of a professional card, samples of the Essences will be sent you at once Write Dept. F 12, Brand & Co Ltd, Mayfair Works, Vauxhall, S W 8

COIN OF AL MANSUR THE FOUNDER OF BAGHDAD THE HEART OF THE ARABIAN EMPIRE

The Caliph Al Mansûr bent upon the establishment of a new capital (the existing one was at Damascus) fixed upon Mesopotamia for its situation. The actual site was chosen for its strategic position. The district, moreover was said to be free from the plague of mosquitoes Double walls with a ditch surrounding them were built and the central area containing the great Mosque and the Royal Palace of the Caliph was further enclosed by a third wall Four gateways led through each concentric circle The city became a great intellectual centre to which students and scholars came from many parts Medical studies held a very high place and no one was allowed to practice as a physician without being able to satisfy the authorities as to his qualifications with the exception of a few of recognised standing The great Rhazes was at one time Physician-in-Chief to the hospital at Baghdad. A high level of civilisation was maintained in Baghdad, until the Tartar invasion in the thirteenth century overthrew it.

Ostomalt

(Ostelin with Malt Extract and Orange Juice)

The success already obtained by Ostomalt as a tonic approved by the medical profession is no matter of chance, but one based upon the scientific accuracy of its elements

The first stages in its preparation take place in the Glaxo Laboratories with their efficient staff of chemists The basis of manufacture is strictly scientific

Ostomalt—consisting of pure malt extract of high diastatic value in combination with Ostelin vitamin D, vitamin A obtained by direct extraction of the cod's liver, and orange juice—contains vitamins A, B, C, and D, in physiologically standardised amounts Each dose can be relied upon for absolute uniformity

Where Ostomalt is administered throughout infancy a normal healthy childhood may be expected, with marked improvement in nutrition and growth It will also be found to serve as a prophylactic against the ailments associated with childhood

In ½-lb and 1-lb Jars
2/6 and 4/-

Free Trials will be willingly sent on request to Glaxo Laboratories 56 Osnaburgh Street, London, N W 1

In view of the importance attached by modern research to correct calcium metabolism, the presence of a calcium salt in certain Ostelin products distinguishes them as preparations which conform strictly to modern scientific requirements.

Three forms in which Ostelin is presented in combination with a calcium salt are specially valuable:

OSTELIN TABLETS

(Ostelin m 1, calcium glycerophosphate gr ii) Particularly indicated for adult use and especially for ante-natal work

OSTELIN EMULSION

An emulsion of Ostelin vitamin D in vegetable oil, with pure calcium glycerophosphate

COLLOIDAL CALCIUM with OSTELIN vitamin D

(for hypodermic injection)

Each ampoule contains 0 5mgm of calcium in the colloidal state, together with Ostelin vitamin D to facilitate and ensure absorption

Free Trials will be gladly sent on request to Glaxo Laboratories 56 Osnaburgh Street London, N W 1

A Paper
ON
FILTERABLE VIRUSES AND PRACTICAL MEDICINE *

BY
S. P. BEDSON, M.D., M.Sc.
SENIOR FREEDOM RESEARCH FELLOW, LONDON HOSPITAL.

I appreciate the invitation to open this discussion, not *as a personal honour, but rather as a compliment* to the laboratory worker, and an instance of that spirit of co-operation between the two branches of medicine—clinical and scientific—which is daily becoming more intimate and consequently more fruitful. There is one point that I should like to bring into prominence. The clinician faced as he is daily with the vital problems of disease should be, and often is, one of the great initiative forces in research. Since my appointment to a research post at the London Hospital I have come to realize how stimulating a close contact with the clinical side of medicine can be to the laboratory worker. But for this to be effective the clinician must have some conception of the lines along which the pathologist is thinking, and I feel, rightly or wrongly, that many clinicians may be out of sympathy with investigation in the field of filterable viruses as suggesting too much of what is termed academic research. I therefore welcome the opportunity of describing some aspects of recent work on this group of disease agents, and hope to show that if something of practical value has already been achieved, the future promises that the laboratory may become of even greater assistance in this realm of disease. I propose, first of all, to discuss very briefly the probable nature of these so-called filterable viruses, and then to deal with the question of immunity in diseases of this class, for it is in connexion with this latter question that much of practical import is going on.

The Nature of Filterable Viruses

Much of the work and speculation which this intriguing problem has incited has merely heightened that atmosphere of mystery with which the unknown is invariably surrounded. This I think, goes a long way to explain the difficulty which the clinician has experienced in approaching the subject. Some have endeavoured to show that these viruses are unorganized enzyme-like agents a *contagium vivum fluidum* as Beijerinck first suggested. Others, while admitting their particulate nature, consider that they represent a form of life differing from that of the cultivable bacteria. Some would even have us believe that they are the product of diseased cells, a product which when brought into contact with fresh susceptible cells give rise to the same diseased state, and in so doing engenders more of itself, the virus thus becoming both the cause and the result of the disease. I do not deride speculation, for I recognize that it denotes a healthy and useful attitude of mind, but it is perhaps unfortunate that much of the speculation which this problem has called forth has served largely to cloud the issue. Surely it would have been better to start from the simpler and more obvious conception that these viruses are akin to bacteria than to evolve an ingenious hypothesis postulating a new form of life and endeavour to make observed facts support it. If one accepts a view of kinship as a working hypothesis, the first question is: Are these viruses living? Now this is not such a simple matter to settle as one might imagine. The line of demarcation between the living and non-living is by no means clearly drawn; in fact there is no single criterion of life. But there are certain characters (such as the power to multiply, to adapt to altered environment, and to assimilate from the surrounding medium without loss of individuality) which, when present together, are characteristic of living things. The filterable viruses possess all these; one is justified in assuming, that they are alive.

Having admitted the living nature of these agents a second question demands solution: this concerns their relation to the bacteria with which we are familiar. One factor, more than any other, has tended to obscure this issue—namely, the limitations of the microscope. Using the visible portion of the spectrum, particles below a certain size cannot be seen with the microscope, although of course, this is a purely artificial limit it has had a profound effect on the way in which the problem of the nature of filterable viruses has been envisaged. We have become so used to staining bacteria and examining them by means of the microscope that we question the bacterial nature of a virus which does not lend itself to demonstration by the usual methods. This has led to the use of viruses being termed ultra-microscopic, but though some of them probably do merit that designation, there are others which are almost certainly within the limits of visibility with the microscope. The bodies described by Paschen in vaccinia virus, which many now hold with Paschen to be the virus, can be stained and seen under the microscope, and the virus of psittacosis is definitely associated with most characteristic bodies which I believe to be the virus. Another example is the virus of fowl pox, so that there seems good reason for stating that "ultra microscopic" is not a character common to this group of viruses. Undoubtedly they are extremely small, as is evidenced by the fact that the majority can traverse filters which hold back the ordinary bacteria, but is this a sufficient reason *for marking them off as something different? I do not* think so. Some of the so-called filterable viruses filter with great difficulty—vaccinia for example—and on the other hand there are visible and cultivable bacteria, such as *Bacterium pneumosintes*, and a number of small saprophytes in the human nasopharynx studied by Olitsky and Gates[1] and by Dochez and his colleagues,[2] which pass through the more porous *bacterial filters*. On the score of size, then, there seems no good reason for separating these viruses from the bacteria, the one group merges imperceptibly into the other.

The inability to cultivate the so-called filterable viruses in a lifeless medium is another reason advanced for assuming that they are not bacterial in nature. For a time our only method of cultivation was in the tissues of the living animals, but the work of Steinhardt and Lambert,[3] Parker and Nye,[4] Carrel and Rivers,[5] and others has *shown that they could be made to multiply in the presence* of living cells in tissue culture, and the Maitlands[6] have further simplified this method of cultivation. Even though we were still unable to grow these viruses apart from living cells, I should hesitate to advance this as a reason for their being unlike bacteria, for there are visible bacteria such as the leprosy bacillus, the cultivation of which in artificial media despite repeated attempts in the past is now a recent achievement which awaits confirmation. Recent work by Muckenfuss and Rivers[7] with the virus of vaccinia would seem to suggest, however, that the virus does not multiply either inside or at the surface of the living cells. Using Maitland's medium which consists of rabbit's serum diluted with Tyrode's solution, added to fragments of fresh tissue, they have obtained survival and possible multiplication of vaccinia virus when the living tissue was separated from the virus by means of a collodion membrane. This would suggest that the function of the living cell is to supply some diffusible substance necessary to the growth of the virus. Should this work be confirmed it may ultimately lead us to a method of artificial cultivation which would remove this apparent difference between the filterable viruses and cultivable bacteria.

No doubt there are competent authorities who will disagree with me, but in my opinion the available evidence strongly supports the view that filterable viruses are bacterial in nature. With each step forward in the knowledge of these viruses the line of demarcation between them and the bacteria becomes less and less obvious, and I look forward with some degree of confidence to the time when the filterable viruses and bacteria will be merged into one large group inside which, of course, there will be minor differences—subgrouping—just as there is in the case of bacteria at the present time.

* Read in opening a discussion in the Section of Medicine at the Annual Meeting of the British Medical Association, Winnipeg, 1930.

Immunity in Virus Diseases

It has become usual to speak of the immunity in virus diseases as being solid and long-standing, lifelong even, in contradistinction to the immunity resulting from bacterial disease, which is so often fugitive, but like most generalizations this is only partially true Undoubtedly recovery from many filterable virus diseases is accompanied by the development of an immunity of high degree and long duration One knows, for instance, how seldom an individual contracts diseases like measles, mumps, or yellow fever more than once But there are diseases due to filterable viruses such as foot-and-mouth disease, herpes, and the common cold—the recent work of Dochez and his colleagues would seem to warrant the inclusion of the last disease in this category[8]—in which the immunity is fleeting and of low grade, just as there are bacterial diseases such as typhoid fever which confer a good immunity Here again the division between the two groups is not absolute

Immunity to a bacterium is associated with the development of antibodies, the presence of which in the blood can be demonstrated in a variety of ways Although the importance of these antibodies in ensuring the immune state varies in the different bacterial diseases, there can be no doubt that either alone or in co-operation with the phagocytic cells of the body they play an important part in the defence mechanism of the organism This is not their only importance, for, of course, they are of the greatest service to us in diagnosis It has been recognized for some time that immunity to filterable virus diseases is associated with the development of specific antibodies which, from the method employed for their demonstration, have been spoken of as neutralizing antibodies During the last few years there has been a tendency to minimize the importance of these antibodies in the vast majority of filterable virus diseases, and to speak of the immunity as being almost entirely cellular—a tissue immunity Recent work, however, has gone a long way to controvert this view, and there seems little doubt that in filterable virus diseases, just as in those of bacterial origin, the two factors—cells and humours—work together in defending the tissues from invasion An active immunity can be obtained against a filterable virus by methods similar to those employed in the case of a bacterium, a virucidal serum can be utilized to procure a passive protection, and with this serum the same immunity reactions that we are familiar with in bacterial diseases can be demonstrated Let us consider these phenomena more closely

Active Immunization

There are two diseases due to filterable viruses against which prophylactic vaccination has been practised for a considerable time I refer to small-pox and rabies In the case of the former disease we make use of the fact that the virus of small-pox when adapted to the cow loses its invasive power for the human organism, so that when implanted in the skin it gives rise to a local lesion only, the evolution of which, however, confers immunity against the virus of small-pox The principle involved—namely, the use of living virus which has been altered by passage through another animal species—is of limited application, for, apart from small-pox, fowl-pox is the only other example of a virus disease in which it is applicable

Although this method of prophylactic immunization is good in that it produces a high degree of immunity, it is not without its dangers Vaccination in Europe has been complicated of late years by an encephalomyelitis with a high mortality It is true that the incidence of this complication is very low, about 1 in 40,000 vaccinated, or 1 in 4,000 of primary vaccinations at a susceptible age But few though these cases are they cannot be ignored, and we must consider what steps are to be taken to avoid their occurrence

The etiology of the condition is still under dispute, some holding that the disease of the central nervous system is the work of the virus of vaccinia, while others maintain that it is due to a dormant neurotropic virus which is stirred up by the vaccinia virus Whichever view may be correct it would seem obvious that the occurrence of such a complication would be minimized or entirely avoided by reducing the amount of virus inserted locally in vaccinating, for the more virus implanted in the skin the greater the amount of virus which will invade the body generally In England this view has led the Ministry of Health to issue an order that vaccination is to be made with one insertion only, with minimal trauma, and at the London Hospital we have employed dilution of the lymph Gins also advocates dilution of the lymph, and it is possible that in Canada the immunity from these troubles has been due in part to the fact that vaccination is less drastic than in Great Britain By still greater attention to the question of dosage the method might possibly be made quite safe, but, personally, I should like to see a method evolved in which inactive or dead virus was used There are considerable difficulties to overcome, however, before such a method will be available

Active immunization against rabies involves another principle—namely, the use of attenuated or inactive virus The classical method makes use of drying to attenuate the virus, but carbolized virus is used with equally good results For long this principle was not considered as applicable to other virus diseases, and the view that the production of lesions with living virus was an essential factor in the development of the immune state was almost universally accepted The observation, made independently by Vallée and his colleagues[9] at Alfort, and by the British Foot-and-Mouth Committee,[10] that the virus of foot and mouth disease could be rendered inactive by low concentrations of formalin and yet retain its antigenic power has put another aspect on the matter I am not claiming that the immunity produced by inactive virus is as solid as that called forth by living virus, I do not believe that it is But the method has its uses, and it has since been shown that vaccines can be prepared by this method from other viruses, such as fowl plague, distemper, and yellow fever The work of Laidlaw and Dunkin,[11] in the prophylaxis of distemper, has been particularly successful They make use of two vaccines the first an inactive formolized vaccine which produces a certain degree of immunity, which is then converted into a solid immunity by the second vaccine consisting of living virus The method has already passed beyond the sphere of experiment, and has been applied in the field with manifest success

In other diseases progress along these lines has not been so rapid Although in France a formolized foot-and-mouth vaccine has been used in the field to a limited extent, in England it is still in the experimental stage In the case of this disease, however, it must be remembered that the spontaneous disease gives only a fugitive immunity, and a further complication is the existence of three immunologically distinct types of virus If an attack of a disease does not confer a durable immunity one cannot hope to achieve very much by the administration of vaccines as a prophylactic measure, and this fact must be borne in mind when considering such diseases as the common cold and influenza, where one attack appears to confer little or no resistance to subsequent ones There is another observation made by Laidlaw and Dunkin in connexion with their work on distemper which puts a check on undue optimism The supply of a filterable virus in any great quantity, at any rate at the present time, is obtained from the tissues of an infected animal In the preparation of distemper vaccine, for instance, use is made of the tissues of an infected dog Both the dog and the ferret are susceptible to this disease, but though a formolized ferret vaccine works admirably in the ferret it is a poor vaccine for the dog, and vice versa, the animal tissues present in the vaccine, when foreign to the vaccinated animal, interfere with the development of immunity to the virus It is easy to see how this will mitigate against the successful application of the method in man, at any rate for the present I make that qualification because much will depend on the progress which we can make in the cultivation of the filterable viruses The work of Muckenfuss and Rivers, which I have already mentioned, gives some hope that this apparently insuperable difficulty will eventually be overcome We had hoped at the London Hospital to evolve a method of vaccination against small-pox on lines similar to those employed in distemper My colleague Dr Bland has carried out a

number of experiments with this object in view, but his efforts so far have not met with success. Formolized vaccine virus inactive to the extent that serial passage in animals will not reactivate it has only produced a very low-grade immunity, insufficient to protect even against a comparatively small dose of active virus. This has been a disappointment, but it should stimulate us to renewed effort. Research has given us a method of prophylactic vaccination against the filterable viruses which has proved its value in veterinary medicine, and I am optimistic enough to hope that further work will overcome the difficulties in the way of its exploitation in protecting man against some of the filterable viruses to which he is susceptible.

Passive Immunity

I mentioned previously that immunity to a filterable virus was associated with the presence of a specific antibody in the blood. The serum of a person for instance, who has had yellow fever, when mixed with yellow fever virus in suitable relative proportions will render that virus innocuous for a susceptible animal: it has neutralized it, hence the term neutralizing antibody. Put the presence of the antibody can be demonstrated in another way, of which I propose to give you an experimental example.

The guinea pig is susceptible to the virus of herpes. Implanted in the shaved hairy skin this virus gives rise to the typical vesicular lesion which characterizes human herpes. If one infects a series of guinea pigs and essays reinfection in them at daily intervals it will be found that seven days or so after infection they can no longer be reinfected: they are immune and it can further be shown that the onset of this immunity coincides with the appearance of a specific herpetic antibody in the blood. Such an immune guinea pig can be hyperimmunized by giving it a series of inoculations of living virus and thereby the neutralizing power of its serum for herpes virus can be considerably increased. Inject 2 c.cm. of such a hyperimmune serum into a normal guinea pig and twenty-four hours later test its susceptibility to herpes virus. It will be found to react very slightly if at all to a dose of virus which produces an intense reaction in an untreated guinea-pig: the guinea-pig has been passively immunized to herpes virus.

This method has its application in human disease, but since one cannot subject individuals to a process of hyperimmunization as was done in the case of the guinea pig use has to be made of convalescent serums. In Canada there is full appreciation of the value of the use of convalescent serum in poliomyelitis, but less, perhaps, of the prophylactic use of measles convalescent serum. Serum collected early in convalescence has a considerable antibody content, so much so that when administered up to the fifth day after exposure to infection in doses varying from 1 to 10 c.cm. according to the age of the person, it will give complete protection and the same dosage given later, from the fifth to eighth day after exposure, though no longer protecting against measles, modifies the attack. In children under 2 years old, in whom measles is a redoubtable disease, one aims at giving complete protection, but in older children, unless they are delicate, it is better to give partial protection, for the modified measles is a trivial affair and the patient gets the benefit of acquiring a solid immunity to this disease.

Although this method has its uses in private practice it has its chief applications in children's hospitals and in the children's wards of our large general hospitals. In the Hospital for Sick Children, Great Ormond Street this method has been applied for some time now, and has proved of the greatest service. It is also in use in the wards of the children's department at the London Hospital and whereas prior to its introduction a case of measles appearing in the ward meant closing the ward to new cases and passing through a period of quarantine now the offending case having been dispatched to the fever hospital, the remaining children receive passive protection and the routine of the ward continues uninterrupted. The great drawback is, of course the difficulty of procuring an adequate supply of convalescent serum. The recent success recorded by Fairbrother[11] in producing an effective anti-poliomyelitis serum in a horse makes one hope that it may not be impossible to produce virucidal serums of effective titre in animals such as the horse and so become independent of the limited and precarious supply of antiserum which convalescents now provide. But here again in the case of active immunization with vaccine [illegible] depend on the progress made with the [illegible] cultivation.

Immunity Reactions

A valuable aid to diagnosis is given by [illegible] as the Widal and the complement fixation tests and [illegible] virus infections give rise to specific antibodies one might expect that these same reactions would be of service in this group of diseases also. Experience is showing that this is the case.

Gordon[12] has shown that with the viruses of vaccinia and small pox both specific flocculation and complement fixation reactions can be demonstrated, and recent work by Burgess, Craigie and Tulloch[13] has demonstrated the practical value of the flocculation test. Small pox in England is almost entirely of the mild type the so-called alastrim, and frequently these cases present difficulty in diagnosis. The flocculation test is performed with a specific serum prepared in the rabbit and a suspension of the crusts from the lesions of the suspected case. The use of this test by Burgess, Craigie, and Tulloch during an outbreak of mild small pox in the South of England and North East England, has shown how very helpful it may be. These investigators examined material from fifty-three cases of small-pox, fifty two of which were of the mild variety, and in only three of these cases was there any difficulty in interpreting the result of the test. The findings with the flocculation test were checked by comparison with the clinical and epidemiological data, and by the result of vaccination during convalescence, complete agreement between the laboratory and field investigations was observed. Further, the crusts from twenty-seven cases of varicella, one case of septic rash, and one of impetigo were examined with entirely negative results.

When it is recalled also that in Great Britain the percentage of the population vaccinated against small-pox is steadily decreasing it becomes evident that the control of this disease will depend to an increasing extent on the early recognition of cases, and the value of a diagnostic flocculation test as an aid to this cannot be over-estimated. The Bordet-Gengou reaction or reaction of complement fixation, is also given by an antiviral serum in the presence of the specific virus. Mention has been made of the work of Gordon with vaccinia and small pox viruses in this respect, and the researches of Netter and Urbain, Wollman, Marie Cinca, and others have shown that this reaction can be demonstrated in the case of other filterable viruses as well. At the London Hospital Dr Bland and I have devoted a considerable time to the study of this question and we have evolved a technique which has given very satisfactory results. The viruses worked with have been the [illegible] vaccinia small pox herpes and zoster and although much of the work has been carried out with hyperimmune [illegible] in laboratory animals we have been able to demonstrate the same phenomenon with serum from convalescents though here the reaction is weaker, as one would expect. In the case of the work on zoster convalescent serum have been used entirely because of the lack of a suitable experimental animal in which to prepare a serum. It is true that difficulties are encountered in performing this test with filterable viruses and its application is limited in certain directions. For instance a vaccinia antigen prepared from the brain of a rabbit inoculated intracerebrally with this virus will not in our hands give specific fixation of complement although one can demonstrate that the antigen contains an abundance of active vaccinia virus. And yet this same brain antigen will produce a serum which will give good fixation with an antigen prepared from vaccinial lesions produced in the skin or testicle. The reason for this is obscure and [illegible] being investigated but despite these occasional irregularities findings we consider that the reaction is virus-specific and capable of considerable service in practice. I will give some examples.

A case of encephalomyelitis was admitted to the London Hospital under the care of my colleague Dr W. E. Brain. The patient had an extensive zoster of the head and neck and symptoms indicative of involvement of the brain and cord which

had developed subsequently to the zoster eruption The question naturally arose whether the encephalomyelitis was due to the zoster virus or not, but since both the vesicle fluid collected from the eruption and the cerebro spinal fluid fixed complement in the presence of known zoster convalescent serums, there was little doubt that the case was in fact one of zoster encephalomyelitis It is true that the reaction given by the cerebro spinal fluid was not as strong as that obtained with the vesicle fluid, but it was nevertheless quite definite and cerebro spinal fluids from cases of encephalomyelitis complicating diphtheria and scarlet fever gave entirely negative results

Recently I have had the opportunity of examining the serum of individuals who had recovered from psittacosis for the presence of specific complement fixing antibodies, and here again I have obtained evidence of a specific reaction Psittacosis may not be so rare a condition as is imagined, and apart from extensive outbreaks like the recent one, where the number and severity of the cases inevitably attracted attention, sporadic cases probably occur from time to time and pass unnoticed The inoculation of animals is too slow a method to be of practical use as a diagnostic procedure, and a specific serum reaction would be a great help in clearing up the diagnosis

It may be said that the examples given are both of rather rare conditions, but the principle is nevertheless of general application In this brief and rather sketchy survey of the present position of research in the realm of filterable viruses an attempt has been made to show that something of practical import has been achieved Undoubtedly an enormous amount remains to be done, but the number of workers in this field is steadily increasing, and on every hand a determined effort is being made to gain a clearer understanding of this group of viruses Some of the problems seem almost insoluble, but it must not be forgotten that the commonplace in bacteriology to-day must have appeared equally obscure to those who preceded Pasteur

MIGRATION AND HEALTH

BY

J S PURDY, D S O, M D, C M, D P H, F R S Ed, F R G S,

METROPOLITAN MEDICAL OFFICER OF HEALTH, SYDNEY, NEW SOUTH WALES

TO DAY the distribution of the white population throughout the British Empire is so important that it warrants consideration not only from an economic and social point of view, but also from the point of view of health

It is perhaps as necessary for Great Britain as for any country other than Japan to organize emigration on an extensive scale, on account of over population After or during every great war, there appears to have been a 'stock-taking" Thus, after the South African war, the English Inter Departmental Committee in 1904 showed that sections of the people, more especially in the more congested centres of population, were liable to suffer from the ill effects of overcrowding, or an artificial, unnatural environment As a matter of fact, there was no evidence of actual physical deterioration, since no previous standard for comparison existed

Actually the average span of life has advanced ten years during the present generation, and man to day has excelled in feats of physical endurance and established records surpassing those of earlier periods We do know, however, that a considerable proportion of people are below an optimum of health and efficiency, physical, mental, and moral Conscription in Great Britain, the United States, and New Zealand during the later stages of the war, brought to light some startling statistics Although it is possible to prove anything by statistics—even the truth—yet it is certainly disquieting to learn that "in the average, out of every nine men of military age in Great Britain, only three were found fit, two were upon a definitely infirm plane of health, three were incapable of undergoing any extra exertion, being practically physical wrecks, and the remaining man was a hopelessly chronic invalid" In Great Britain alone, a million men examined at the recruiting depots were found to be not sufficiently fit to be worth training for war service owing to structural defects or organic disease

In regard to conditions to day, the following passage occurs in Mr and Mrs Sidney Webb's monumental work, *The History of the Poor Law*

"Is there any condition more sordidly tragic than the lot of the youthful unemployed—to day counted by the hundred thousand, under nourished physically undeveloped, empty minded, loungers in disconsolate groups at street corners, or aimlessly tramping from one casual ward to another—a prey to all evil influences?"

In Australia and New Zealand, although the conditions under which the masses live are vastly better than in Great Britain, still it is comforting to read the statement of the late Professor Cunningham, the distinguished anthropologist

"In spite of the marked variations which are seen in the physique of the different classes, anthropologists believe, with good reason, that there is a mean physical standard, which is the inheritance of the people as a whole and that no matter how far certain sections of the people may deviate from this by deterioration the tendency of the race as a whole will always be to maintain the inherited mean. In other words, those inferior bodily characteristics which are the result of poverty (and not vice, such as syphilis and alcoholism), and which are therefore acquired during the lifetime of the individual, are not transmissible from one generation to another To restore, therefore, the classes in which this inferiority exists to the mean standard of national physique, all that is required is to improve the conditions of living and in one or more generations all the ground that has been lost will be recovered"

The Anzacs

Together with the sister overseas Dominions of Canada and South Africa, Australia and New Zealand offer a field for studying the effects of what is or ought to be *generally* a healthy and natural environment on a people, for the most part at least, only one or more generations removed from the parent stock of the British Isles, or, in the case of parts of Canada and South Africa, people from France and Holland Sufficient data have already been collected with regard to school children to show that the improved environment has had a beneficial effect Records collected by the late Mr Symons and myself for the New Zealand Health Department in 1908 and 1909—quite as extensive as to numbers examined as the data available to witnesses at the time of the Inter Departmental Committee—were especially interesting in showing that, while the average stature at the ages of 11 to 12 of boys in the public schools in England in 1883 was 54 98 inches, that of the cadets of the Auckland Grammar School and King's College was 56 inches at the same age Contrasting the heights of boys at Marlborough College, England, with those of King's College, Auckland, and Wanganui College, we found that between the ages of 14 and 15 the figures were 61 96 for the famous English public school and 63 for the New Zealand schools Even more interesting was the fact that a comparison between the boys of the Chapel Street School, Auckland (probably the children of the poorest parents of the largest New Zealand city), with the boys of Remuera (the wealthiest suburb), showed less disparity than the measurements and weights of children in the poorer districts of English cities as compared with the children of the more prosperous parents residing in the suburban centres and the boys of the English public schools Such a result was only to be expected in a country where there is not the severe handicap of poverty—such a dead weight in some of the congested centres of Great Britain Moreover, the prowess of the young Australian and New

* A paper contributed to the Section of Medical Sociology and History of Medicine at the Annual Meeting of the British Medical Association, Winnipeg 1930.

Zealander in the field of war or of sport need not make him ashamed to meet the stranger either within or without his gates

Dr Harvey Sutton Director of the School of Hygiene and Tropical Medicine, Sydney, late Principal Medical Officer to the Education Department New South Wales, has shown by statistical tables and graphs that the individual Australian boy or girl is physically superior to the Australian born with one British parent and the latter to the child with both parents born overseas judging by height and weight Whether the comparison is made in the metropolis, town, or country, the more Australian the child the better the physique The rural child of whatever "Australianship has been shown to outstrip the child of the large country town and of the metropolis between these the difference is much slighter Although the Australian figures for recruiting examinations have not been properly analysed, where three out of nine were classified A1 in England about four in every nine were up to the standard in Australia The C3 class was certainly smaller The predictions of school hygienists in regard to the findings of from 50 per cent to 60 per cent of defectives in schools were thus verified Dr Sutton points out that the defects in the years of school life prove to be the basis of the later physical deterioration

Thus all is not well, even in Australia Lieut General the Honourable Sir Neville Howse V C, K C B the distinguished Director-General of Medical Supplies of the Australian Imperial Force later Australian Minister of Defence and Minister of Health expressed grave doubts in 1921 whether 50 per cent of Australia's young men were fit for active service In a note on the health of the young male Australian written in reply to a request by myself, as to the percentage of those volunteering for service who were fit he stated

'The necessary information is not available to make an authentic statement but a certain amount of reliable evidence does exist which lends support to my belief

(a) Out of 21 000 senior cadets born in 1905, who were examined, 13 6 *per cent were found unfit for transfer to the Citizen Forces* notwithstanding that many medical officers passed a number whom they recognized would never be fit for service but who would, in their opinion be benefited by a few years of physical training

(b) Dental examination of Citizen Forces at camps of training shows that a large proportion suffer from dental defects unfitting them for active service

These facts together with the appalling number of men who during the war were found, on examination unfit not only for active service but for strenuous civil employment are a travesty on public health. Speaking generally and comparatively however, the good physique of the Australian Imperial Force was conspicuous—as might be expected in a voluntary army from a country blessed with a good climate good stock and with a people given to outdoor life and sport—even in our cities which possess a healthful open air environment where slum conditions are few and overcrowding has not existed long enough to cause any deterioration of type

The analysis of the present population of Australia shows that 97 per cent are of British origin and actually 99 per cent are British subjects Although Australia and New Zealand have the greatest natural increase of population in the world except Quebec at the present rate of natural increase—the difference between births and deaths being only 2 per cent per annum—we would have 12 million people in thirty years even if we did not get a single immigrant and at least 50 million in a century through natural growth, actually as many people as there were in the United States of America at the end of its first century

Ellsworth Huntington, in *Civilization and Climate* makes out a convincing claim that climate is the chief factor in the development of a nation A mean temperature of 64° F a mean humidity of 80 per cent and frequent changes of temperature are the best conditions for physical work He shows that people who like the Scotch live under conditions of relative storminess, become industrious capable and successful

McCollum, on the other hand in *The Newer Knowledge of Nutrition*, emphasizes diet as the prime factor in the development of a people He ascribes for instance the rise and progress of the Canadians in contrast with the high improvidence and retrogression of the people of the B ha ma —both descended from a common loyalist stock who emigrated from the Northern and Southern States rather than live under the Stars and Stripes—not so much to the highly stimulating climate of Lower Canada in contrast to the mild and uniform climate of the Bahamas as to the difference in diet The Bahamas produce tamarinds, olives, lemons oranges, limes, citrons pineapples, pomegranates, figs bananas melons yams potatoes cucumbers sugar, maize and peas or fruits and vegetables not unlike those of Queensland and the Northern Rivers district of New South Wales but their bread and meat are imported. The people of Lower Canada subsist mainly on cereals peas beans potatoes meat milk cream butter and cheese—a diet similar to that of the people of Australia

With regard to the Australian national diet D T Sawkins, in a memorandum to the New South Wales Board of Trade, states

The average food supplies per head of population remain the most important factor in determining national physique It is hard to avoid the conclusion that the comparatively superior physique of the Australian soldiers was built up on the liberal average diet of the decades before the war Then, the average gross supply of meat in New South Wales was 240 lb to 290 lb in contrast to the present [1922] consumption of 170 lb to 200 lb per man per annum. If this great change in the national diet is to stand for any considerable period then a great change may be expected in the national physique

Equally true with the dictum that an army fights on its stomach is it that the fate of nations depends upon how they are fed and as my old teacher Professor E. J Hamilton used to say It is better for a man to have a good stomach than a good head.

As far as the health and longevity of the individual is concerned, however second only in importance to being begotten of a healthy long lived stock or parentage is the food of the mother during his pre natal life and his diet in infancy The first fundamental requisite to rear a healthy race is of course that children should be fed as Nature intended them to be at the breast of mothers who have themselves been well nourished by a well balanced vitamin and mineral-containing diet of which fresh milk salads and fruit should be the chief constituents

The superior physique of the pastoral peoples of the past as of the present is chiefly the result of a generous milk ration One cannot visit the Hawkesbury District of New South Wales without commenting on the fine physique of the people undoubtedly due as far as the earlier generation is concerned to a diet of milk, maize meat fruit and other fresh foods rich in vitamins and mineral constituents combined with a life in the glorious sunshine and fresh air It is regrettable that resort to the grocery store rather than to local farm produce and the feeding of whole maize to the fowls rather than to the children is not maintaining the fine physique of the Hawkesbury native The cornstalk a New South Wales type with a reputation for lankiness and thinness is the immediate successor of the Hawkesbury native A visit to a Hawkesbury race meeting shows that the older generation consists of tall brawny well made big men Mr J H M Abbott hailing from the Hawkesbury River Flats, writes

The first of the free settlers who commenced the march westwards squatted there and owned the land by right of occupation. If they could obtain them, they took wives unto themselves and reared up families And the families subsisted principally on pumpkin and ground maize and wore no boots in their childhood, and led a free wild, untrammelled sort of life So they grew into tall, clean limbed, deep-chested men, and sturdy comely women, and spread north and west and south over the land—and their offspring were the fathers and mothers of the Cornstalks of to-day

The Analogy of the Merino

The people of Australia to-day owe a great debt to Captain John MacArthur of Camden Park, who imported the first merino sheep in 1796 The pioneers were told that the climate was unsuitable and that the merino wool would deteriorate as the sheep were taken nearer the Equator At the beginning of last century the heaviest fleece grown weighed 3½ lb., whereas actually a fleece of 35 lb was recently

cut from a stud sheep The merino sheep to day, however, is very different from the original stock Some of the direct descendants are still to be seen at Camden Park Various strains have been crossed with the original blood—Saxon, Negretti Infantado, and, above all, the French Rambouillet Thousands of the last strain were brought to Australia in the first half of last century So readily did they adapt themselves to their new environment that it was speedily recognized that this type was ideal for producing fine wool under our special conditions of sunshine, climate, and green pasturage Since then the great sheep breeders have evolved a truly national Australian merino, quite distinct from all the older strains of Europe—greater in every respect, greater, indeed, than any other variety of the breed in any other country in the world

Two young Englishmen of French extraction—the Pepins—must be credited with the actual development of the merino as it is known to day In 1861 they began to build up a stud flock at Wanganella, by purchasing a ram, now famous under the name of "Emperor," a big well proportioned plain-bodied, outstanding animal with strong head and horns So well did he mix with the Wanganella ewes that he became leader of the stud The progeny of the other imported animals was gradually eliminated, until the whole flock became inbred to him

Various sheep breeders since the day of the Pepins, like the Falkiners, the Austins, the Mills, the Millears the McKaugheys, and others, by careful selection, judicious mating, and heavy culling, have improved each generation until now our large flocks are bred to type with variations according to climate and soil Stamina above everything else is the quality demanded Pampering is anathema to the big breeders Science has come to the assistance of the stud masters For instance, Professor Brailsford Robertson says that 'if any one of the amino acids that build the tissues of the sheep is lacking in the food supply of the animal, the whole of the rest of the food becomes valueless as far as building up the tissue is concerned"

The industry of sheep breeding is now being conducted on a more scientific basis Who can say whether sheep at the end of the present century will not be carrying twice the fleece they carry to day, when they average 8 lb per sheep, instead of the average of 3 lb half a century ago? If we could apply the same system to the human element in Australia—that is to say, cull by the elimination of the unfit, especially the mentally unfit, and select the best type of immigrant, physically, mentally, and morally—we would still further improve the present breed Certainly the fine agricultural country type of Englishman, Irishman, and Scotsman, predominating before 1820, which may have deteriorated to a certain extent by the industrialism of the later years of last century, is being reproduced in Australia, South Africa, Canada, and New Zealand by a type which bids fair to be even better in physique

The Growth of Population in Australia and Canada

The causes of emigration are stated to be adversity, economic distress, and the attraction of the prospect of wealth and improved conditions, apart from the earlier causes, such as political or religious oppression The great migration between 1841 and 1847 when 2½ million people left Ireland, mainly for the United States, was caused by the years of potato famine As far as Australia, including Tasmania, is concerned, although in the early days a certain number of people are said to have left their country for their country's good, undoubtedly many of them made good in the new country, as was the case also with Virginia and Maryland in America, where those transported became in many cases industrious and exemplary citizens

Australia to day is peopled by immigrants or the descendants of immigrants There is no one living in Australia (other than the aborigines) who is a descendant of the fourth generation of Australians We have actually an area of 3,000,000 square miles, nearly equal to that of the United States of America, four fifths of that of Canada, over one-fifth of the area of the whole of the British Empire—that is, more than three quarters of the whole area of Europe, and actually twenty five times as large as Great Britain and Ireland We have a population of only 6½ million, while Great Britain and Ireland have a population of roughly 50 million As a matter of fact, the Dominions overseas, embracing Canada, Australia, New Zealand, and South Africa, have only about 18 million whites It is to be remembered, however, that five thirteenths of Australia is within the Tropics

In spite of the distance from the Motherland, the population of Australia since Governor Phillip landed 141 years ago has shown phenomenal growth, especially in the last hundred years During this period it has grown to the same size as that reached in Canada in three centuries The most conservative estimate of the population that Australia could accommodate has been stated to be 40 million The Right Honourable William Morris Hughes estimated that Australia could maintain a population of 100 million, while some have put the figure as high as 200 million

While Canada occupies one sixteenth of the world's area, it has only one two hundredth of its population The first settlement in Canada was at Port Royal or Annapolis, Nova Scotia, in 1605 By 1763 there were 90,000 people, in 1800 a quarter of a million, whereas now there are 10 million In Canada to day 78 per cent of the people are native born, while only 11 per cent are British born

As showing how history repeats itself, the Napoleonic wars, just like the last war, created tastes, habits, and conditions incompatible with the peaceful activities of the new era that followed The total population of the world in 1800 was 700 million, whereas it is 1,900 million to day During that time the population of England and Wales increased from 12 million to 38 million

Immigration Problems

The problem of the distribution of population throughout the British Empire is not so simple as it might appear The mere transfer of the surplus population from one part to another which is sparsely populated, so far from solving the problem of unemployment, may tend to aggravate it In Australia it is extremely difficult to absorb some immigrants, especially those whose ways and ideas have been set before they arrive, youths under 20 years, provided they are of reasonably good stock, can be made into good Australians Older people find the conditions so different from their previous environment that they have difficulty in accommodating themselves

One method of settling immigrants has been that of the group settlements in the south west of Western Australia, where immigrants receive 160 acres of land and 10s a day for two and a half years These settlements are well described in *Amateur Settlers* by Lord Apsley, who found that one third of the settlers within an area abandon their holdings He ascribed seven failures out of ten to ill health Mr W Banks Amery, British Dominions Office Representative in Australia, found that 32 5 per cent of British settlers either abandoned their holdings or were dismissed Of 1,105 Australian settlers, 45 per cent left their holdings or were dismissed Thus actually among "stickers" 68 per cent were recent British arrivals and 59 per cent native born Australians A Royal Commission found that one of the difficulties was the dislike of the women for dairying, and the preference of numbers of men to work for wages rather than accept the responsibility of fending for themselves It was also found—as in the case of the returned soldiers from the war for whom many millions were spent in settlement on the land in Australia—that poor and unsuitable land had sometimes been selected The opinion now prevailing is that these settlers should be placed only on first class land, that payment should be by piece work, and that they should be drafted into preliminary training camps Altogether there have been 135 groups of settlers, which have provided a population of 9,580 at an expenditure of 3½ million pounds

The Big Brother Movement, by which boys are brought out to Australia and placed under the protection of citizens, as the boys brought out under the Dreadnought Fund, has been satisfactory

The general impression of the people with regard to the immigrants that arrive is that they are less than "fair average quality" Most of the States welcome land workers and

domestics, but do not encourage other immigrants except nominees—that is those who have friends already in the country prepared to assist them

Where the medical profession might do great work for the Empire is by encouraging a suitable type of youth to emigrate one with a good family history of good physique ambitious and above all with a will to work Dr Stewart Mackintosh's observations[1] suggest that readiness of adaptation to change argues an ancestry derived from many and varied stocks such as are usually bred together by urban influences One result of the rapid transition from an agricultural to an industrial nation has been the disintegration of rural communities their aggregation in new centres and the extraction by a severe process of natural selection of types that could adapt themselves to industrial exigencies and climatic and other conditions The New World has drawn some of its most hard working labourers from limbos of despair, men who develop a surprising physique and energy as soon as they can enter environmental conditions at all conformable to their physical needs Professor Karl Pearson emphasizes that it is essentially the man who makes his environment and not the environment which makes the man We have chosen to make ourselves an industrial nation and allow our agriculture to decay, we have offered industrial work to those who made their living on the soil luring them into the cities and into environments differing in many respects from those in which they were brought up

A few sons of medical men have come out to Australia since the war, received some training at the Hawkesbury Agricultural College and in some cases are doing well on the land to-day If anyone cared to organize a batch of sons of medical men, it would not be difficult to arrange for them to be met on arrival and have them distributed to sheep and cattle station owners or farmers in Australia and New Zealand on similar lines to the Big Brotherhood Movement Certainly if they came out with the intention of settling and marrying the Australian girls who are even a finer type than the men, would give them a hearty welcome

RADIUM TREATMENT OF EPITHELIOMATA OF THE SKIN*

BY

ROY WARD M.B., B.S.

THE RADIUM INSTITUTE, LONDON

IN this opening paper I propose to deal mainly with the subject of basal-celled epithelioma or rodent ulcer and to touch briefly on the question of squamous epithelioma believing as I do that this disease has a surgical rather than a *radiological* aspect

RODENT ULCER

Radium is undoubtedly the best treatment in most cases of rodent ulcer it is in this condition that the most striking and permanent results of radium therapy are obtained Excision is equally effective in some cases but owing to the difficulty in excising completely even a small growth from the situations most commonly affected radium is to be preferred Cosmetically it gives results which cannot be obtained by any other method, the resulting scar being supple and the skin almost normal in appearance X rays will cure a number of these lesions but the treatment is tedious, and the action of the rays cannot be limited with such great accuracy Recurrences are more frequent, and permanent healing is not so certain

Clinical Varieties.—A rodent ulcer usually begins as a smooth, waxy, semitranslucent pearly nodule which grows very slowly, often assuming the form of a rosette of nodules with a raised margin and depressed centre A growth such as this belongs to the early hypertrophic variety and frequently shows cystic degeneration More nodules may appear and coalesce, thus forming a larger hypertrophic growth, or, owing to some slight trauma, the growth may break down, with the formation of a brownish scab Gradually there develops a superficial ulcer with a gelatinous base and the raised pearly margin both characteristic of the disease The ulcerated area may heal over in one part, leaving a smooth atrophic scarred area while in another part the disease continues to advance This is known as the superficial flattened cicatrizing type which has a characteristic braided margin Both the hypertrophic and superficial ulcerative types may reach a considerable size, but generally remain limited to the surface The disease may, however, extend deeply to reach the underlying tissues penetrating muscle and bone, thus giving rise to deep irregular cavities Such lesions of the deeply ulcerative variety seldom have the typical rolled edge the margins are usually indurated and sharply cut with a well marked inflammatory zone surrounding the ulcer Although there may be extensive local destruction of tissue, these growths never give rise to metastases unless they assume the clinical and histological appearances of a squamous-celled epithelioma It is very important to recognize this transitional type The relative frequency of the various types can be shown from an analysis of 1 773 consecutive cases treated at the Radium Institute, London

Type of lesion.	Relative frequency
Hypertrophic (small and large)	51 per cent
Superficial	
Ulcerative	30
Cicatrizing	3 "
Deeply ulcerated	16 "

The following shows the results for each group

Type	Apparently cured.
Hypertrophic	91 per cent
Flat	77
Deeply ulcerated	33 "
All cases	77

Many of the last group were such that healing was out of the question, owing to extensive involvement of bone and cartilage

Sites.—Rodent ulcers are most common on the face The most frequent situations are the nose and cheek, as shown in the following table

Nose	763	Chin	36
Cheek	377	Mastoid	22
Inner canthus	193	Trunk	21
Lower eyelid	151	Neck	20
Temple	141	Upper eyelid	19
Forehead	93	Lower lip	17
Ear	84	Eyebrow	12
Outer canthus	56	Scalp	10
Upper lip	47	Hand	4
Preauricular	37		

Etiology

The disease is more common in men than in women—953 patients were male and 820 females The youngest patient under treatment was a girl who was first seen at the Radium Institute at the age of 19 She was sent on account of a deeply ulcerative lesion which affected the inner canthus and had started as a nodule at the age of 12 It will be seen that the disease is most common between the age of 60 and 70

Age	Frequency
10–20	1
20–30	11
30–40	63
40–50	213
50–60	394
60–70	464
70–80	332
80–90	82
90–100	2

Multiple lesions are more common than is usually supposed There were 94 cases in this series 55 were in men and 39 in women. In one case a woman aged 28, had as many as nineteen different lesions treated with radium

Previous Treatment.—A number of patients had been operated on once or several times, and many had received treatment by x rays or radium at other hospitals The disease had either recurred or had become resistant to

* A paper read in opening a discussion in the Section of Radiology at the Annual Meeting of the British Medical Association Winnipeg 1929

repeated x-ray treatments It is interesting to note that of the 240 patients whose lesions had previously become refractory to these rays, 102 were healed as the result of radium treatment, 32 were improved, while the remainder did not show any improvement or the results were not recorded

Transitional Type.—Occasionally, as already pointed out, an undoubted basal-celled growth takes on the characteristics of a squamous-celled epithelioma When this occurs the disease progresses extremely rapidly There is early involvement of the lymphatic glands, and death occurs from cachexia and septic absorption There were 40 such cases in this series, in 25 the lesions were situated in the neighbourhood of the ear, and in 11 of these they actually started in the pinna It is interesting to note that all these patients had received repeated exposures of radium, and 11 had had previous x-ray treatment In all there was marked secondary infection, no doubt an indication of lowered resistance

Diagnosis.—The clinical diagnosis of a rodent ulcer is comparatively easy Since there is a possibility that biopsy tends to activate a growth, it is our custom to confirm the diagnosis microscopically only in doubtful cases

Treatment.—The fundamental principle, in this as in other conditions, is to estimate the dose sufficient to bring about the death of all the malignant cells without impairing the vitality of the surrounding normal tissue, so that healing will take place satisfactorily The more radiosensitive types may be treated successfully by various techniques, and this probably accounts for the similarity in the results obtained at various radium centres, although the methods adopted are in many cases quite different In discussing treatment it is advisable to consider each variety separately, the technique employed is determined by the type of lesion and the structures affected

Small Hypertrophic Growths

Growths extending only a little beyond the surface and mobile on the underlying structures should be treated by surface radiation Exposure to the unscreened full strength applicator is the method of choice This apparatus is a solid plaque containing 5 mg of radium element per square centimetre, the whole of it is covered with thin rubber tissue to prevent contamination by discharges All crusts must first be removed, and it is wise to protect the surrounding skin by rubber-covered lead sheeting in which a hole has been cut a little larger than the lesion, so that any outlying groups of cells may be treated The apparatus should be applied for one to two hours, according to the thickness of the lesion

The applicator emits a strong intensity of beta rays, which are sufficiently penetrating to reach all parts of the tumour As a result of the beta radiation an erythema is noticed in about ten days, reaching its height in about three weeks Over this inflamed area a crust forms, which dries and falls off towards the sixth week, leaving a soft and supple scar When it is necessary to limit the irradiated area on account of the proximity of especially sensitive organs, it is advisable to use buried radium in the form of screened seeds

Large Hypertrophic Growths

It is particularly important in these cases to adopt a technique which will result in a homogeneous distribution of the rays to all parts of the tumour under consideration, so as to avoid any stimulating action which may be produced at the limit of the zone of action It is therefore necessary to use screened apparatus Probably the most useful procedure is to employ needles buried in and around the growth The needles most commonly employed have walls of 0·3 mm of platinum, and contain 2 mg of radium per centimetre of active length As a rough guide to the technique it may be stated that no part of the growth should be further than one centimetre from a source of irradiation, and it should be remembered that more massive doses should be placed at the periphery in order to obtain a homogeneous distribution If needles were placed at the same distance throughout the growth, the centre, being irradiated by its own foci as well as those adjacent, would be exposed to a greater dose than the periphery

Various modifications of this technique are employed with equally good results Some authorities prefer a comparatively large dose for a short time, while others advocate exposures for ten days, and sometimes even as long as thirty days It has been the practice at the Radium Institute never to increase the time factor beyond seventy-two hours' continuous treatment So radio-sensitive are these tumours that equally satisfactory results are obtained by either method It is the rule for complete cure to ensue even in advanced cases, providing they are of the purely hypertrophic type

The Superficial Ulcerative Variety.—These are at first small hypertrophic growths which have ulcerated superficially at the centre, leaving the remainder of the growth as a rolled edge Their treatment is similar to that of the hypertrophic growths from which they originate In the case of small ulcers, which are mobile on the deeper structures, an unscreened applicator should be used for one and a half to two hours A cure is almost invariably obtained. Larger ulcers in which there is much subjacent infiltration must be treated by other methods By using a light screen, such as 0·1 mm of lead, the less penetrating rays, which only act near the surface, are absorbed, leaving a more penetrating but weaker radiation, which must be employed for a correspondingly longer time The full strength applicator, thus filtered, should be applied for two to four hours, according to the amount of infiltration present

The Superficial Cicatrizing Variety.—This type should be treated in the same way by unscreened radium plaques It is necessary to irradiate a considerable distance beyond the visible margin of the growth as outlying columns of cells are undoubtedly present in these situations

The Deeply Ulcerative Variety.—This is the most severe form of basal-celled epithelioma and the most difficult to treat Gamma radiation must be used, beta radiation with unscreened or lightly screened radium is not suitable The method of employing Columbia paste plaques for prolonged periods of two to three weeks has been advocated for this form of rodent ulcer The results are usually unsatisfactory and frequently disastrous, for, although in the course of these long applications the rays have more chance of finding the neoplastic cells at the moment of their greatest fragility, it is no less certain that the normal cells of the surrounding tissues are also affected adversely The prolonged irradiation of the normal cells, and those already debilitated by the spread of the disease or by secondary infection, may result, not only in a radium necrosis, but in increased activity of the neoplasm It is therefore advisable, in order to avoid the disadvantages of prolonged exposures on the one hand, or insufficient screenage on the other, to employ much larger amounts of radium screened through a minimum of 2 mm of lead or its equivalent for a comparatively short period In addition, means must be found to absorb the secondary radiations, and sometimes this is done by the interposition of Columbia wax or sorbo rubber, a measure which also provides a more homogeneous dose, by the distance which is created between the radium and the lesion With this technique the duration of treatment varies between forty-eight and seventy-two hours If the time is increased beyond a total of seventy-two hours, damaging effect may be produced, especially in old people Although, of course, it is desirable to destroy all the neoplastic cells to avoid recurrence, this should never be done at the expense of destroying the adjacent tissues, the integrity of which is so necessary for satisfactory repair Recently the use of needles or screened seeds has in some cases replaced or supplemented surface treatment Needles are either inserted into or laid along the growing edge In many of the more extensive lesions better results have been obtained by using this form of treatment than with a plaque of uniform intensity Such are the lines along which the deeply ulcerative type should be treated when limited to the soft tissues If, however, bone or cartilage has been invaded, an even shorter exposure will be advisable, since these structures, especially when devitalized by the invasion of the neoplasm, have a great tendency to radium necrosis The results in this class of ulcer are not so good as in the former types About one-third of the cases treated become healed, but many cases show

little or no improvement Should no improvement be noted within two months, surgical treatment, such as excision with the diathermy knife and subsequent skin grafting, should be considered In the more advanced cases it is exceptional to obtain a cure, but a large proportion show improvement with temporary arrest of the disease

Repetition or Irradiation Treatment

There is no doubt it is best to give a maximum dose at the *first treatment, for after each successive dose a* rodent ulcer becomes more refractory to treatment It is supposed that repeated treatments cause some degree of radio-vaccination On the other hand, a growth which has proved refractory to beta radiation will often respond to gamma radiation A second exposure in those cases in which no healing has been obtained is usually of no use, and may only aggravate the condition If however complete healing has not occurred, but a definite improvement *is noted and there is still some induration left, a second* treatment with a thicker screen may be required to affect the deeper limits of the lesion Previous treatments produce an avascularity of the tissues rendering them more susceptible to radium necrosis

Radium should never be employed within six weeks of any previous treatment When it is decided to give a *renewed treatment it is important to know whether a patient has had previous x ray treatment The age of the* patient, the details of the previous dose and its subsequent reaction, must all be taken into consideration It is important to estimate the dose so as to avoid a 'radium burn' Infection readily takes place, and an intractable ulcer forms which may take months or even years to heal The term 'radium burn" is often used incorrectly, being applied to the simple vesication and ulceration which follow upon an unscreened radium exposure, and which are an essential part of the reaction In these cases a destructive reaction has been *deliberately produced for a definite* purpose and satisfactory repair can be anticipated The term 'radium burn" should be reserved for the few instances in which the dosage has been excessive The resultant ulceration may be extreme in degree, pain is severe and persistent, and repair is always slow

Prognosis

This depends on the age of the patient, the type of growth, its position, and the extent of the disease when treatment is commenced In old people there is less resistance offered by the surrounding tissues to the advance of the disease Ulcers of the hypertrophic group usually respond exceedingly well to irradiation The flattened cicatrizing type shows a tendency to recurrence, and ulcers of the deeply ulcerative group are not so suitable for treatment, in fact, the value of radium in very advanced cases is doubtful, the patient's resistance to the disease is poor and the power of repair is deficient When the lesion is small radium treatment is usually successful It is only when the disease extends to the deeper tissues and infiltrates underlying bone or cartilage, that the prognosis becomes grave

Ulcers in certain situations such as the forehead ear and inner canthus, have a serious prognosis When a mucous membrane is implicated, the condition also proves more resistant, and is often only eradicated by free excision When an ulcer becomes secondarily infected it often responds poorly to radium In some cases the sepsis appears to be aggravated by treatment, thereby only adding to the patient's discomfort

Squamous Epitheliomata

Squamous epitheliomata of the skin differ from rodent ulcers in their more rapid growth and in their formation of metastatic deposits in the neighbouring lymphatic glands These lesions are susceptible to the rays of radium although not to the same degree as the basal-celled growths The warty type in particular may be readily destroyed by irradiation, whereas ulcerative lesions prove more resistant In the early stages of the disease the results of excision are so good that radium should be reserved for the more extensive cases In patients treated with radium a high percentage of cures has resulted, nevertheless the growth should be excised in operable cases and this should be done with the diathermy knife

When radium treatment is considered advisable gamma radiation must be used, interstitial radiation being the method of choice Needles of low content should be employed with walls of 0·6 mm of platinum and containing *0·5 mg of radium element for each centimetre of* active length They should be introduced into the healthy *tissue in the immediate vicinity* of the growth, and allowed to remain in position for a week By the end of six to eight weeks the resultant reaction subsides and the growth gradually disappears, leaving a smooth scar The primary growth should not be regarded as apparently cured unless the treated area is perfectly soft Any residual induration should be excised, as this may be the nucleus of a rapidly growing recurrence Prophylactic doses of radium to the neighbouring lymphatic areas are of doubtful value

When the glands are definitely invaded the prognosis is very grave In these cases needles or Columbia wax plaques may be employed The immediate result is often encouraging but the permanent disappearance of infected glands is exceptional Much can be done to relieve symptoms and prolong life but in its later stages the disease proves resistant to all forms of treatment

THE TREATMENT OF LATE SYPHILIS.

BY

THOMAS FERGUSON, M.D., F.R.C.P.Ed., D.P.H.,

FORMERLY MEDICAL OFFICER IN CHARGE OF VENEREAL DISEASE DEPARTMENT DARLINGTON GENERAL HOSPITAL.

During the past six years I have made increasing use of bismuth preparations in the treatment of late cases of syphilis It had been my usual practice to treat such cases with bismuth intramuscularly, and with mercury and iodide orally during the first three months continuing *thereafter with combined bismuth and arsenical therapy* Finding that in a considerable number of cases the Wassermann reaction became negative after the first three months course I decided to try the effect of more prolonged bismuth treatment instead of exhibiting the arsenicals

The bismuth preparation used in this series of cases was neotrepol, of which 1 c.cm is equal to 0·03 gram bismuth 2 c.cm of it were given weekly so that in the normal three months course each patient received 2·03 grams bismuth together with 1·260 grains potassium iodide and 210 grains hydrargyrum cret One month's rest was given between each course and the number of courses given ranged from two to six

Records are available of 46 consecutive cases treated on this plan The Wassermann reaction of 24 of these had proved resistant to previous arsenical treatment while 22 had had no previous treatment whatever

Clinically the results were striking Only two cases—one of central nervous system syphilis and the other an advanced heart lesion—failed to respond and the amelioration of symptoms was so marked that it was difficult to persuade many of the patients of the need for further treatment

The influence of treatment on the blood Wassermann reaction, if less dramatic, was notable In 30 cases (65·2 per cent.) the Wassermann reaction was rendered negative, in 13 cases (28·1 per cent.) the strength of the positive reaction was reduced and in only 4 cases (8·7 per cent.) did it remain unaltered Of the 30 cases in which the Wassermann reaction became negative 9 did so after *the first course 7 after the second 4 after the third and* 4 after the fourth Of the 13 cases in which the strength of a positive Wassermann reaction was reduced 5 received only two course of treatment and 5 had three, while of the 4 cases in which the Wassermann reaction was uninfluenced, 2 had two courses and 2 had three

The results in the cases which had resisted arsenical treatment differed little from those obtained where no

treatment had previously been employed—62 per cent of the former became negative and 68 per cent of the latter

Of the 46 patients dealt with, 12 presented no symptoms when referred for treatment, *although several of them* were mothers of children showing clinical evidence of congenital syphilis The Wassermann reaction in 11 of these cases was made negative, in the other it remained unaltered Sixteen showed tertiary syphilitic lesions which had been present for over a year, the Wassermann reaction was made negative in 7 of these and remained unaltered in 2 In the remaining 18 cases the lesions, *though tertiary, were of more recent appearance*, in 12 of these the Wassermann reaction was made negative, while in 1 it remained unchanged

In only 22 of the cases was the approximate date of infection known In 12 the disease was of less than ten years' standing, and of these the Wassermann reaction was made negative in 7, the other 10 were of longer duration, and 4 of them became sero-negative It was noted that the clinical and serological results in cases of late skin lesions were particularly good Three of the cases in which serological improvement occurred were at one stage of their treatment sero-negative, but *subsequently relapsed* One of these patients attended for treatment very irregularly, and only received three courses in two and a half years

The patients tolerated the treatment well, though in three cases it was necessary to suspend it for a few weeks, twice on account of gastro-enteritis, and once on account of severe stomatitis One other case developed a fine scarlatiniform rash, which came up within twenty-four hours of each bismuth injection and gradually faded away during the remainder of the week It caused her no inconvenience, and her treatment was not interfered with

The average patient will stand three such courses during the first year of treatment and two during the second, and, if the patient can be given five such courses, the Wassermann reaction will be rendered negative in about 70 per cent of cases Many will be sero-negative much earlier, in this series over 80 per cent of the cases began to show serological improvement by the end of the second course

It must be remembered that these are cases of old-standing disease, often occurring in elderly subjects, for recent infections arsenical treatment is essential I am convinced that in *many of these old cases bismuth* is even more efficient than arsenic, and that the safety, ease, and rapidity of administration, and its relative cheapness, render it of great practical value

PUERPERAL SEPSIS.*

BY

E FARQUHAR MURRAY, M D, F R C S,

HONORARY OBSTETRIC PHYSICIAN TO THE PRINCESS MARY MATERNITY HOSPITAL, NEWCASTLE UPON TYNE

THE strict measures adopted at the Princess Mary Maternity Hospital, Newcastle-upon-Tyne, to prevent contagion produced vastly improved results, some details of these were published in the *British Medical Journal* of May 3rd (p 814) It would not be fair to attribute all the improvement to the new routine, a "scare" regarding sepsis has a tonic effect on nursing in general

There should be a larger proportion of fully trained nurses on the staff of maternity hospitals, especially for the nursing of *suspect and septic cases Clean* and suspect cases cannot be nursed together, the former are endangered, and the latter tend to be neglected The problem of *isolation is one of great anxiety*, as many maternity hospitals are quite unequal to the demand made on them They were designed before the notification of puerperal pyrexia produced such an influx of febrile cases requiring hospital treatment, which at times tends to convert them into fever hospitals

* Summary of a paper read before the Edinburgh Obstetrical Society

The following would appear to be the minimum requirements of a modern maternity hospital (1) an admission room for preliminary classification, (2) examination room and wards for (*a*) clean, (*b*) suspect cases, (*c*) cases of genital sepsis, (*d*) cases of extragenital sepsis Each of the four units should have its own labour ward and nursing staff

The present method of recording morbidity in maternity hospitals is largely valueless owing to the indiscriminate grouping together of cases The only reliable record is that made of clean cases that are delivered in hospital

The periodic pyrexial wave among suspect cases admitted to hospital was studied from 1925 to 1930 When compared with clean case (Group B), which have similar complications, but for whose safety from sepsis the hospital is *primarily responsible*, it will be seen that the outside cases have a higher sepsis curve, but that there is a degree of sympathy between the curves

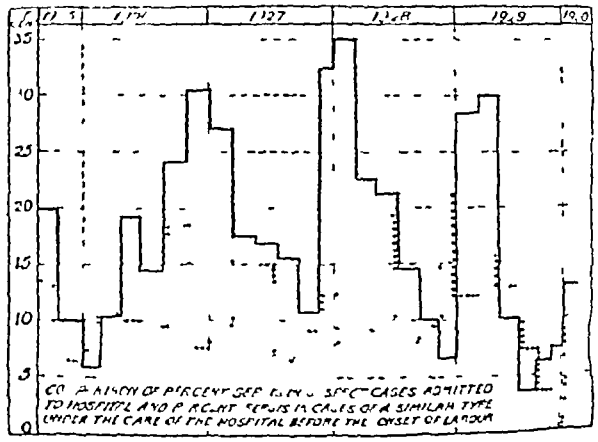

CHART 1

Thick black line = percentage sepsis in suspect cases sent *into* hospital Dotted line = percentage sepsis in Group B clean cases delivered in hospital

In looking for the cause of these pyrexial waves, it seemed reasonable to exclude the hospital because, with its admitted defects *during some of the years* in question, there was no reason why its own cases should not follow a similar curve The possibility of periodic overcrowding was excluded, as the numbers admitted, especially of suspect and septic cases, were remarkably constant

Since the pyrexial waves occurred during the winter months, I wondered if, during periods of epidemics, doctors were perhaps too rushed to devote sufficient time to maternity work This theory was investigated by studying certain types of cases which were sent in during the four months of highest pyrexia and the four months of lowest pyrexia for the years 1926, 1927, and 1928 Cases of "failed forceps," haemorrhages, abnormalities, and eclampsia were studied

Suspect Cases

	High Sepsis		Low Sepsis	
	No of Cases	Percentage Septic	No of Cases	Percentage Septic
Failed forceps	18	33	24	15
Haemorrhages	57	21	54	13
Abnormalities	50	32	77	10
Eclampsia	18	39	22	10

The results of this investigation completely exonerated the profession Not only did it reveal that the septic factor is one which is general and not selective, but—still more important—that a larger number of cases of failed forceps and abnormalities were sent in by doctors during periods when they were slack and when the sepsis rate was low than when they were busy and the sepsis rate was high

The seasonal character of the waves suggested that they might correspond to period of general lowering of the individual resistance to infection Dr H Kerr, medical officer of health for Newcastle, provided a list of deaths of both sexes occurring from influenza and pneumonia during the years 1925 to 1930 There is a marked similarity between the death curve and the sepsis curve (ee Chart 2)

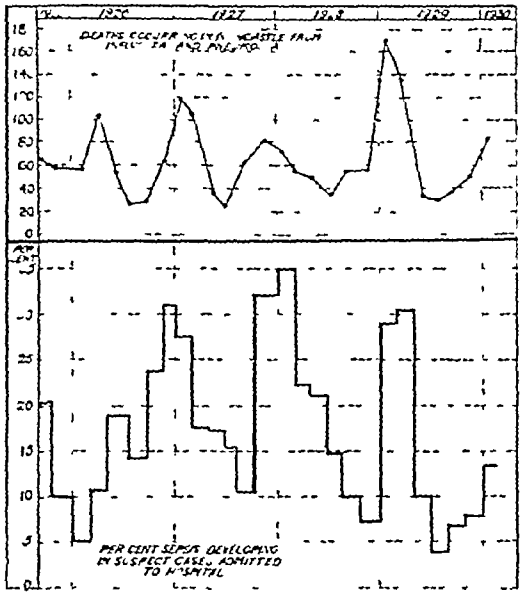

CHART 2

The difference between the sepsis curve of cases sent into the hospital and cases of a similar character which have been under the care of the hospital remains to be explained If the seasons or the hospital were entirely to blame, then the curves should have been identical The following difference existed between hospital and outside cases

High Sepsis

	Hospital		Others	
	No of Cases	Percentage Septic	No of Cases	Percentage Septic
Haemorrhages	25	16	57	21
Abnormalities	59	9	50	32
Eclampsia	8	Nil	18	39
Low Sepsis				
Haemorrhages	24	8	51	13
Abnormalities	83	15	77	10
Eclampsia	4	Nil	22	10

With only one exception the hospital cases showed better results This suggested that under existing conditions many patients of the industrial class do not get as good medical and nursing supervision as they obtain in hospital It will be readily understood by anyone with a practical knowledge of the subject that cases sent to hospitals by doctors are not necessarily "doctors" cases and, even when they are, the doctor in charge has too frequently been without skilled nursing assistance

Conclusions

1 The liability to puerperal sepsis is greater at certain seasons than at others

2 Its incidence can be considerably modified by proper medical supervision and adequate nursing attention

RESPIRATORY COMPLICATIONS FOLLOWING SURGICAL OPERATIONS DURING A FOUR-YEAR PERIOD *

BY

D C AIKENHEAD, M D,

LECTURER IN CLINICAL SURGERY UNIVERSITY OF MANITOBA

THE subject of respiratory complications following surgical operations has been a source of worry to all concerned, while endless controversies have arisen as to the part inhalation anaesthesia plays as a causative factor There was a time when almost every post-operative complication except haemorrhage was put down to the latent influence of the anaesthetic The whole of the anaesthetic vapour necessary to produce anaesthesia passes through the lungs to the patient, while 90 per cent is excreted by the same route, any abnormal post-operative lung trouble was so easily ascribed to 'irritation from the ether Time heals all things,' and during the last decade the etiology of respiratory complications has changed the extensive use of novocain for major surgical procedures, with subsequent pulmonary lesions, has brought forcibly to mind the realization that other factors besides ether irritation enter into respiratory complications

"I have flowers from many gardens, but only the string which holds them together is my own" In the following analysis of lung lesions following a four-year period in a large general hospital, the only claim I make for originality lies in the compilation of data peculiar to this hospital and geographical situation, and I can only touch upon a few of the salient features

Series of cases giving the pulmonary complications following surgical operations vary widely in the ratio to numbers of operations, so much so that comparisons are of limited value An extensive review of the literature dealing with the subject varies in the interpretation of the end-result, yet there is agreement upon some points Thus, for example, patients who undergo upper abdominal operations and those with gross sepsis have a high ratio of post-operative pulmonary trouble, as compared with patients free from gross sepsis and not submitted to abdominal operations Considering the magnitude of modern surgical procedures it is remarkable that respiratory lesions are not more frequent

STATISTICAL RETURNS FROM OTHER HOSPITALS

For comparative purposes I am including a limited number of reports from other hospitals These comparisons are not invidious since such factors as climate, surgical technique and the type of operation suggest a wide variation in the end result

Silk [1] in 1897 reported 5 000 operations, 13 with respiratory complications Of these 13 cases, 5 followed operations upon the tongue or jaws Thirty years ago laparotomies were not entered upon so lightly as at the present day Mikulicz and Henle[2] record that of 1 767 upper abdominal operations 145 (8 per cent) were followed by lung lesions Mikulicz asserts that as many respiratory complications follow after local as after general anaesthesia Armstrong[3] in 2 500 major operations in Montreal reports 55 cases (2.2 per cent), and Feather stone [4] in a most exhaustive review of the literature quotes 222 gastric cases from Birmingham, with a morbidity of 10 81 per cent Whipple,[5] at the Presbyterian Hospital New York reported upon 3 719 patients of whom 97 (2.3 per cent) developed post-operative lung lesion Elwyn,[6] from the wards of the Mount Sinai Hospital New York states that in 299 operations under some form of local anaesthesia 11 patients (2 7 per cent) contracted some form of pulmonary trouble In 1922 I published a brief survey [7] of 7 000 operations followed by 19 respiratory complication

* A paper read in opening a discussion in the Section of Anaesthetics at the Annual Meeting of the British Medical Association at Winnipeg 1930.

STATISTICS OF THE HOSPITAL

The statistics now to be reported consist of 33,066 operations performed during the four years 1926-29, 31,301 operations were under general anaesthesia, and the remaining 2,765 were conducted under some form of local anaesthesia. According to the hospital records there were 55 respiratory complications with 23 deaths.

Methods of Induction

Before going into a detailed analysis of these 55 cases a few words giving the pre-operative routine might not be out of place, probably about 65 per cent. of the patients would have a preliminary injection of 1/6 grain of morphine sulphate, combined with 1/150 grain of atropine sulphate. We rarely use large doses of morphine. Great care is exercised in excluding from operation patients with a cold or coryza, even if afebrile. In cases with a history of recent respiratory trouble or tonsillitis operation is postponed for two to four weeks.

More than half of this series received ether dropped upon a thick cotton fabric supported by a wire frame, a mixture of two parts of chloroform with three parts of ether was added in any operation where ether would not induce sufficient relaxation by itself. Nitrous oxide and ethylene were administered by McKesson machines, one in six would be a rough estimate of gas anaesthesia. Post-operative ward treatment varied widely according to the individual clinician. The gravity of the operation ranged from excision of a sebaceous cyst, and brief dental extractions, to thousands of appendicectomies and herniotomies, and severe operations upon patients with grave renal or cardiac conditions. The ages of the patients ranged from 4 days to over 80 years.

One feature which emerges most prominently when first looking at the morbidity of this series of cases is the number of patients with additional pathological changes to that for which the operation was designed to relieve. Kipling states: "Indeed when you come to think of it, had the British Army consistently waited for reserves in all its little affairs, the boundaries of our Empire would have stopped at Brighton Beach."

Nature of Cases with Ensuing Respiratory Complications

Of the 55 patients with respiratory complications in this report, 13 had sequels of a minor nature, 7 infarcts, and there were 6 cases of pleurisy, the remaining 42 suffered from pneumonic processes. These 42 cases included 9 emergency operations, 16 patients (including 7 of the previously mentioned) had marked elevation of the pulse, temperature, and respiration at the time of operation. Nine patients were over the age of 60, and in 23 (more than half) the operation involved the gastro-intestinal tract, including herniotomies.

Another interesting point is the gravity of sepsis at the time of operation, 23 of the 42 patients with major complications died, and at the time of operation 19 of these 42 had gross sepsis. Of these 19 patients with sepsis, 14 died (73 per cent.). Twenty patients out of the 55 originally mentioned were first-class operative risks with one death, this may be compared with the 35 substandard patients with 22 deaths.

In 1929 of 1,772 abdominal operations (excepting 242 thyroidectomies), there were 6 respiratory complications with two deaths, both patients who died were over the age of 70, and the operations were emergency ones. In the same hospital in 1922, Dr. H. Morrison[8] reported upon 408 patients operated on for appendicitis, with one death from pneumonia. Broadly speaking, this report agrees with the ratio of respiratory lesions given for 1929—a morbidity of 6 in 1,772 cases.

The sexes were approximately equally affected in this series. Some writers have stated that respiratory complications occur more frequently in males than females, owing to the interference with the abdominal type of breathing rather than with the thoracic type characteristic of women. As regards age, each decade over 40 adds to the operative risk. Fair comparisons of the type of operation are difficult to establish. An American writer has stated that post-operative pulmonary complications occur in 14·8 per cent. of stomach operations, and in 5 per cent. of operations upon the gall-bladder, averaging altogether 7·7 per cent.

No definite conclusion can be reached as to the influence of the length of operation. A number of the poor risk patients had short anaesthesia periods and succumbed. It might be said, however, that the shorter the time under a general anaesthetic the less interference would there be with the vital processes of the body. Gas anaesthesia carried with them a higher ratio of pulmonary lesions than ether, but in many instances gas anaesthesia was given in preference to handicapped patients. Neuhoff[9] reports 500 necropsies following surgical operations. Pneumonia was diagnosed previously in 81 cases and found after death in 51 subjects, or 60 per cent. He states also that "a diagnosis of post-operative pneumonia in such patients is fraught with difficulty, and the classical physical signs of pneumonia do not prove its presence in serious post-operative conditions." In addition, Neuhoff found pneumonia a much more common cause of death in clean wounds than in infected wounds, 11 per cent. in the former, 1·5 in the latter.

Theory of Lung Infection

The splinting of the abdominal muscles due to pain in the wound and tight binders causes more or less circulatory stasis in the bases of the lungs. This area of stasis is invaded by infection passing up the lymphatics through the diaphragm. Collyns believes that atelectasis and pneumonia are different phases of the one process. He states: "In the atelectatic portion of the lungs the vessels exude a sticky secretion. This secretion prevents the passage of air, and consolidation follows, after consolidation infection follows so easily."

CONCLUSIONS

1. Post-operative pulmonary complication is a serious hazard to recovery, 40 per cent. of the patients died in this series. Of 13 patients with elevation of pulse and temperature at the time of operation 11 died (84 per cent.).

2. Taking into consideration the number and gravity of modern surgical procedures, pulmonary complications following operations are less numerous than might be expected. In this series 15 per cent. of the patients were 70 years old, and 21 per cent. had elevation of the pulse, respiration, and temperature at the time of operation.

3. Sepsis (gross) at the time of operation is a greater risk than post-operative pneumonia.

4. Careful selection of patients, and pre-operative measures with equal attention to the matter of after-care, will keep the incidence of respiratory lesions down to the minimum, until such time as a definite cause is known for this dreaded operative sequel.

THE INFLUENCE OF LACTATION ON OVULATION AND OESTRUS

BY

J. T. CUNNINGHAM, M.A., F.L.S.

ACCORDING to Crew and Mirskaia[1] oestrus and ovulation occur in the mouse within twenty-four hours of parturition, and if no fertilization then takes place there is no second oestrus for an interval of twenty to twenty-five days, which is the normal duration of lactation. This interval, called the lactation interval, cannot be appreciably lengthened by prolonging the actual lactation by means of supplying new litters of young, but on the other hand, if the original litter is removed at a shorter interval—for example, seven or fourteen days after birth—oestrus recurs on the second to fourth day after such removal. They state that, according to the evidence of experiment, lactation causes the

corpora lutea of the first post partum oestrus to persist, and that these corpora lutea inhibit oestrus during the lactation interval. The theoretical explanation proposed is that the stimulus of sucking acts on the anterior lobe of the pituitary, and that the excess of pituitary secretion so produced causes the persistence of the corpora lutea.

The weakness of this theory is that there are many animals in which lactation does not inhibit oestrus. In the ungulates—the cow, mare, and sow—according to Parkes, lactation has no effect on the recurrence of the oestrous cycle, and therefore pregnancy or ovulation. In the human species the occurrence of menstruation during lactation seems to be quite common but not without exception. In cases where there is no succession of short oestrous cycles the question of the effect of lactation does not arise; for example, in the dog pregnancy lasts about two months, and is followed by lactation for about the same period, and there is no recurrence of oestrus during all this time but oestrus is also absent for a similar period when no pregnancy or lactation occurs.

The case of the ferret, recently investigated experimentally by Hammond and Marshall is in strong contrast to that of the dog, though both animals are carnivores. Oestrus in the female ferret is marked by a conspicuous feature—namely, great swelling of the labia of the vulva. Ovulation occurs only after copulation and in the absence of this, oestrus continues till the end of the breeding season. The duration of pregnancy is forty-one or forty-two days, and the recurrence of oestrus after parturition depends entirely on lactation. When the young were killed immediately after birth oestrus began nine days later, but while lactation continued there were no signs of it. Moreover, during lactation the corpora lutea do not remain large, as in the rat, but rapidly atrophy, as in the rabbit, from which it would appear that the influence of lactation in suppressing oestrus does not act through the medium of the corpus luteum.

Another instructive contrast is afforded by the rat or mouse and the guinea-pig. Both genera are polyoestrous, the cycle in the rat occupying five to six days, in the guinea pig about sixteen. In the guinea pig, there is no lactation interval, there is, as in mouse or rat, an immediate post partum oestrus, followed by a second at the normal interval of sixteen days during lactation. As the suppression of oestrus only occurs in the mouse when more than two young are suckled, the absence of oestrus—suppression in the guinea-pig has been attributed to the smaller number and greater maturity at birth of the young in this animal.

According to the results of O'Donoghue[2] and Hartman[3] the difference between the marsupials *Dasyurus* and *Didelphys virginiana* is similar to that between the dog and the ferret. The former is monoestrous and oestrus is absent not only during the period of lactation but during the corresponding period when there are no young in the pouch. In *Didelphys virginiana* on the other hand in the absence of pregnancy oestrus recurs every twenty-eight days but is suppressed during the whole of lactation, the young remaining in the pouch about fifty days. But if the young are removed from the pouch and destroyed oestrus returns ten to fifteen days later.

It is not possible to discuss details at greater length in such an article as the present, but enough has been stated to prove that there is no general correlation between the stimulus of sucking and the suppression of oestrus as is assumed by the theory of Crew and Mirskaia. This correlation occurs in the mouse and rat, in the ferret, the rabbit and the Virginian opossum, but it is absent in cow, mare, goat, pig and frequently if not always in the human species. It seems to me that the really significant correlation is between the suppression of oestrus and the condition of the newborn young. In those cases where oestrus is inhibited the young are naked immature and kept for the greater part of the time enclosed in a warm nest in close contact with the mother. In the other cases where oestrus occurs during lactation, as in the cow and the guinea pig, the young are born covered with hair and able to run almost at once. If the inhibition of oestrus were due to the absorption of soluble substances by the mother from the bodies of the young, either from the mouths of the latter through the teats or from skin to skin, the correlation between the ridiculous immature condition of the young and the suppression of oestrus during lactation would be explained, while on the theory of the stimulus of sucking, since this stimulus occurs in the cow as in the mouse, there is no reason for the difference between the two in respect of oestrus during lactation. The case of *Didelphys* is especially important, for here the young are born after a gestation of only thirteen days in an early foetal stage of development, and are transferred to the pouch where they become permanently attached to the teats. The skin within the pouch is naked, vascular and glandular, and removal of the young from it has the same effect with regard to oestrus as removal of the foetuses from the uterus in higher mammals. The stimulus of sucking maintains the process of lactation in all cases, whether in the cow or the opossum, and it has been shown in the opossum and in the rabbit that the stimulus determines secretion, not in the whole system, but in each gland individually, but it is improbable that it affects the occurrence of oestrus.

How the hormones supposed to be absorbed on the theory I have suggested could affect the recurrence of oestrus, whether by acting on the corpora lutea or on the pituitary, is a matter for future investigation, but it may be mentioned that in most cases there is reason to believe that substances absorbed from the foetuses in the uterus determine the persistence of the corpora lutea. Considering the atrophy of the latter after abortion, it is a question whether it is the function of corpora lutea to maintain pregnancy, as frequently stated, or the effect of pregnancy to maintain the corpora lutea.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL

FOREIGN BODY IN THE CAVERNOUS SINUS

A case similar to the one here recorded was reported by J. F. I. King in the *British Medical Journal* of October 30th, 1926, where a woman fell on her face and struck her head against some wood outside her cottage door. Six pieces of wood were found in the cavernous sinus and she died of meningitis, orbital abscess, and a cerebral abscess in the right temporal lobe. In the present case there was only septic meningitis.

A man aged 40 was admitted into the General Hospital, Colombo, under the care of Dr. Lucian de Zilwa with a history of fever of ten days' duration.

Some time ago he was walking in his garden when a coco-nut branch fell on his head, causing a small wound just above the inner canthus of his left eye. He was treated at the Victoria Memorial Eye Hospital where the surgeon extracted a small piece of splinter and treated the external wound. In a few days he developed fever and headache and later became very drowsy. He was then transferred to the General Hospital. Examination revealed a penetrating wound above the inner canthus of the left eye. He was semi-comatose and did not answer any questions. There was bilateral proptosis, the pupils were dilated and inactive, the left being more dilated than the right. There was no paralysis. The lungs, heart and abdomen were normal. *Further examination could not be carried out as the patient died within two hours of admission.*

Post mortem Examination.—On opening the skull evidence was found of septic meningitis. There was a thin layer of pus over both hemispheres anteriorly—more marked on the left side. The left cavernous sinus was occupied by a thrombus in which were embedded two pieces of splinter. One piece measured 1·2 inch by 1/5 inch, the other was smaller. Pus and yellow material in the thrombus had been caused by suppuration. There was also a thrombus in the right cavernous sinus. Extravasations of blood and minute pieces of splinter were found along the floor of the left orbit. The eyeball was not damaged, nor were the orbital muscles. There was no fracture of the bones of the orbit.

The absence of damage to the eyeball was remarkable. The splinters must have been driven with considerable

force to have entered the cavernous sinus The passage of the splinters was probably along the orbit through the sphenoidal fissure straight into the cavernous sinus

I must thank Dr Lucian de Zilwa for permission to publish this case

CYRIL F FERNANDO, M D , M R C P Lond ,
Assistant Pathologist, General Hospital, Colombo

TREATMENT OF RHINOPHYMA

THE remarkable improvement in a case of rhinophyma as the result of surgical intervention seems worthy of record

A man, aged 47, had suffered from rhinophyma for ten years, but had not had medical advice because a friend had informed him that if anything was done he would bleed to death He

was, however, recently persuaded to consult me, and I took him into hospital for an operation Anaesthesia was induced with open ether, chloroform was then given with a Junker's apparatus

Removal of the growth was effected with a scalpel, and presented *no difficulty*, the only neighbourhood requiring care being that around the nostrils, where the growth had invaded the nares, and new nostrils had to be fashioned Haemorrhage, though free, was very easily controlled by swab pressure and a few forceps The wound was dressed with acriflavine emulsion on gauze, and had quite healed in ten days, when the patient was discharged

The most striking feature of the case was the change in the patient's morale From having been afraid to go about, he is now a very happy, cheerful, and grateful fellow

I am indebted to my partner Dr R H Blair for the photographs of the condition "before" and "after"

Camborne R SHEARSMITH COLDREY, M B , B S

A CASE OF SOMNIFAINE POISONING

THE following case should be of interest to all who are accustomed to prescribe somnifaine in cases of insomnia, and to those who intend employing the drug

At 7 30 p m on April 29th, I was called to see a man, aged 73, who had been found by the police lying unconscious in an open field, and had now been brought to a suitable place for treatment A perfectly new 12 c.cm bottle labelled "Somnifaine" was found empty beside him

On examination his pulse was regular and normal in rate and tension breathing quiet and normal, and eyelids closed His pupils were slightly dilated and the conjunctival reflexes were present Any attempt at moving his arms or legs was feebly resisted Strychnine 1/15 gram was injected hypodermically, and I left him in the charge of a nurse, stating that there was no cause for alarm

Four hours after the injection the nurse reported that he muttered a few words, but relapsed into sleep again Forty eight hours after my first examination the man awoke slightly confused and very hungry, but otherwise none the worse for his protracted sleep He *admitted drinking all* the somnifaine (12 c cm) at one go, but asked to be spared further questions 'as it was a painful subject"

Somnifaine is supplied as a liquid hypnotic in 12 c cm bottles, and the label bears in small red lettering the word "poison," in accordance with Part I of the Regulations "1 c cm contains 0 1 gram diethyl-barbituric acid and 0 1 gram allyl-isopropyl-barbituric acid in the form of salts of diethylamine" A medium dose is 25 drops, and I find by measurement that the man took eight times the medium dose

Reviews.

CLINICAL RADIOLOGY OF THE ALIMENTARY TRACT

THE first volume of the series of works on the clinical radiology of the gastro-intestinal tract, edited by Pierre Duval, J -Ch Roux, and Henri Béclere, was published in 1927, and dealt with affections of the stomach and duodenum This work has recently been followed by two volumes which together form an atlas of the clinical radiology of the oesophagus, intestine, liver, and other accessory intestinal glands the authors are Professor J GATELLIER and MM F MOUTIER and P PORCHER, all of the faculty of medicine of Paris

The arrangement adopted by the authors is very convenient for the reader, in the text they give a full account of the methods used and of the disorders illustrated in the radiograms, and to each photograph they append an explanatory drawing with a brief description The first volume opens with a study of the oesophagus Among the radiograms are some showing slight variations from the normal, including unusual contractions, the appearances of compression from without stenosis, cancer, diverticula, and fistulae, and a mega-oesophagus which held two to three pints of fluid In the chapter on the jejunum and ileum, a part of the gut that often receives but scant attention, there is a good picture of an obstructing gall stone in a loop of small intestine lying in the left iliac fossa

The authors state that the right colon is normally a mobile organ, though the mobility may vary in degree, and show how volvulus of the caecum may arise from inversion, rotation, or transposition Among the illustrations of abnormal positions of the caecum are some showing its penetration into diaphragmatic and scrotal hernias, and a skiagram of a case of congenital abnormality in which the right colon is seen to be situated entirely in the left side of the chest, the caecum being at the level of the apex of the left lung A full account is given of redundancy of the sigmoid, the characteristic of which is regarded as length, whereas the distinguishing feature of megacolon is increased diameter

In the second volume the authors discuss and illustrate the radiographic evidence of colitis Their statement that there is no individual x-ray feature characteristic of this condition will not, we believe, meet with general acceptance, for many radiologists can recognize with certainty the disordered segmentation of colitis The signs of colitis they classify as static and kinetic, the latter including abnormalities of filling, spasm, and disorders of emptying The authors point out that spasm should be taken to indicate disease only when it is constant in different postures Acceleration of the rate of passage occurs frequently, material arriving at the sigmoid flexure in nine hours and being evacuated within twenty four Static signs are short sigmoid segmentations, inhibition, a lessened diameter of the lumen, variable spasms, and areas of gas The appearances resulting from adhesions are dismissed shortly, but the investigator in this field soon learns that the signs of fixation are only presumptive, not certain The authors point out specially that a low position of the bowel is no evidence of immobility

In discussing cancer of the colon the authors state that they find the barium meal valuable in establishing the state of the lumen—this is, the canalization The enema is given with the patient in the prone position, on the assumption that the flexures are thus more readily passed, in some cases atropine is given to make the filling easier Arrest of the head of the meal, they point out, is of little diagnostic importance unless it coincides with evidence of a tumour

Nearly one hundred pages of text and pictures are devoted to the radiology of the accessory glands—namely, the salivary glands, the liver, the gall-bladder, the spleen,

[1] *Radiologie Clinique du Tube Digestif* (Clinical Radiology of the Alimentary Canal) Publiée sous la direction de P Duval J Ch Roux et H Béclere II *Oesophage, intestin fois et glandes annexes* Par J Gatellier, F Moutier et P Porcher Clinique Thérapeutique Chirurgicale de la Faculté de Médecine de Paris Fascicule I et II Paris Masson et Cie 1930 (Roy 4to pp 389 416 radiographs, 427 figures Foreign edition, 330 fr the 2 volumes, bound)

and the pancreas. The illustrations include skiagrams of biliary, renal, and pancreatic calculi *in situ*, with notes on their differential diagnosis, pictures of the biliary and pancreatic ducts and an attractive plate of 79 radiograms of biliary calculi with a table of their relative densities. Most of the photographs are good, and many have unusual interest. The descriptions are carefully worded, and in some sections of the work are to be found facts and illustrations that would not be easily available elsewhere. These volumes are likely long to remain a standard work for radiologists and practitioners.

THE MECHANISM OF EVOLUTION

PATHOLOGY as a factor in evolution should have a special interest for the medical profession. But it has been left to Mr MORLEY ROBERTS to explore that avenue, and in *The Serpent's Fang*[1] he has further elaborated the views expressed in his earlier works *Warfare in the Human Body*, and *Malignancy and Evolution*. He is a sociologist turned biologist, which gives him a fresh and individual outlook. he is also a bonny fighter and those who differ from him must expect some shrewd blows.

The sight of a viper on Exmoor stimulated an engineer to ask Mr Morley Roberts how a serpent's fang became long, curved, hollow, and movable. That a mechanism so complicated could arise by the accidental addition of accident to accident, each minute and spontaneous, was too much for an engineer to believe. He would as soon have attributed the modern steam engine to a similar set of causes. Now there are many to-day who faced with evolutionary theory, are in like case with that engineer. Here as elsewhere rigid orthodoxy is proving incredible, and is maintained by an act of faith rather than by reason. Dr Russell Brain in his little book *Galatea, or the Future of Darwinism* (which was reviewed in our columns on June 16th, 1928, p. 1029), pictures the course of evolution according to Neo-Darwinians thus: "Imagine a company of people setting out from London and deciding their destination by opening at random the pages of Bradshaw, and taking a ticket for the first town on which their glance alighted. Suppose them to repeat the process on reaching their first destinations and assume that there is a law by which all who are unfortunate enough to hit upon a second town which is not on the same line as the first are forthwith executed." This would not appear to be a rational mode of locomotion nor would it achieve much. But it would be simplicity itself compared with the course of evolution as pictured by rigid Mendelians and followers of Weismann. Can we really believe that mutations are fortuitous and owe nothing for their origin to environment when it is only in relation to environment that they have any value. Mr Morley Roberts cannot believe it. But he feels that if the strict Darwinian view is denied in favour of a modified Lamarckism, even this is itself incomplete and must be added to. That Darwin himself, with his addiction to use and disuse was more Lamarckian than he knew is nowadays quite clear. That natural selection is an exceedingly severe censor on unsuitable mutations is evident. That many critics of Lamarck neglect his insistence on the importance of the time factor must be admitted. But the whole question has been looked at too exclusively from the morphological standpoint and the importance of function in determining structure has been disregarded. "For life *is* function." Perhaps Mr Roberts is a thought too sceptical of genes and chromosomes which he regards as mere tools with which the cytoplasm works. But the special contributions he has made to the theory of evolution are the conception that the tissues of the multicellular organism exist in a state of lotile symbiosis, and that breakdown and repair are important as forerunners of new developments.

Such views explain a great deal. If each tissue is competing within the individual body to obtain the best possible conditions for itself we can understand why the individual is himself the scene or conflict why isolated cell unrestrained by other tissues acquire a positively malignant growth and why a strong central nervous system is needed to maintain order. All this is in accord with Wilfred Trotter's demonstration of the way in which the nervous system insulates and virtually protects it from its rebellious subjects in the soma. Further if the effort to overcome obstacles is a recognized factor in development, surely the obstacle of disease must be one that most irresistibly calls out such effort. The last enemy that shall be overcome is death, and the approach of death by disease will be strenuously combated, successful combat is rewarded by new adaptations.

But if Mr Morley Roberts finds the heaping of accident upon accident such an inadequate explanation, the reader must not suppose he believes in evolution by design. Far from it, he reserves his choicest satire for those who seek short cuts to a final explanation of the universe. Particularly does the abstract philosopher come under his ban. There is much better work to be done in this world than to chop logic at the bar of the Absolute.' He even dislikes Spemann's idea of a differentiator which determines the course of development and it affords him some gratification to link it up with that other fantastic quasi-deity the 'censor' in the latest psychology.' His last chapter entitled "Obscurantism and Biology" affords entertaining reading even though one may feel some sympathy for the victims of his lash. In Mr Morley Roberts's view "to leave the laboratory bench and assume the mantle 'star-enwrought' of the metaphysician harms the whole cause of science."

He would push the scientific method as far as possible, and not have any commerce with attempts to solve the insolvable. But such attempts will always have their attraction for the human mind, although, as Dr Charles Singer says, all the cosmologies which have been constructed to provide an explanation of the world become, in course of time, an obstacle where they were once an aid.

AMERICAN GYNAECOLOGICAL PRACTICE

THE new edition of ANSPACH'S *Gynecology*[2] has been brought up to date by the inclusion of the most recent advances. The first part gives a complete account of the development, anatomy and physiology of the pelvic organs and calls for no special comment. This is followed by a survey of methods for the examination of patients together with a general account of the significance of the various signs and symptoms that may be encountered and is a section of the book that will be appreciated by medical students. The various gynaecological diseases are then considered one by one each special organ being dealt with in turn. Syphilis tuberculosis and gonorrhoea have each a special chapter. A full account of operative technique and of post-operative treatment forms an important section of the book.

It is perhaps a pity that some less well-established methods have been given places in prominence equal to those which time has shown to be sound. At the present time the treatment of functional disorders of menstruation by administration of ovarian extracts can scarcely be regarded as standing on a satisfactory basis yet in this textbook the limitations of their uses are not sufficiently pointed out. The more recent work on the diagnosis and treatment of sterility due to blocking of the Fallopian tube is very fully considered but here again a more critical attitude towards this branch of gynaecology would have been better. There is an excellent chapter on "backache" in which the importance of orthopaedic causes is stressed. Full consideration is paid to the diagnosis and treatment of such cases and although the subject is strictly speaking outside the province of the gynaecologist he is so frequently confronted with the symptom of backache that it is important to have a clear plan of all its causes. A short review of the part played by radium and deep x rays in the treatment of carcinoma and in the production of an artificial menopause is given at the end of the book but in view of the importance of these methods the details of the technique employed might well have been fuller in a work as comprehensive as this.

[1] *The Serpent's Fang*. By Morley Roberts. Lond.: Evelyn Nash and Grayson Ltd. 1930. (Demy 8vo. pp. 253. 18 net.)

[2] *Gynecology*. By Brooke M. Anspach, M.D. With an Introduction by John G. Clark. Fourth edition, revised by the author with the assistance of Philip F. Williams, M.D. London: J. B. Lippincott Company. (Med. 8vo. pp. xvi + [illegible]. 56 figures. 42s. net.)

The book is well written throughout, and although its outlook is typically American its clear enunciation of first principles may make it appeal to British students As an account of established American practice it is very useful as a book of reference, and its value in this respect is enhanced by the inclusion at the end of each chapter of an extensive bibliography The references, it is true, are drawn mainly from American and German literature, but this makes them the more valuable in this country Like most American books, it is profusely illustrated, but on more careful consideration one wonders whether some of the illustrations might not have been omitted without loss to the clarity of exposition

HYDROTHERAPY

THE practice of hydrotherapy in a French institution is well described by DR DUBOIS DE SAUJON in a small book entitled *L'Hydrothérapie médicale*.[4] His is one of several special installations which are conducted under medical direction, and in which the treatment is often administered by the medical man himself In this volume he gives a clear and brief outline of the physiological action on the organism of applications of water, and describes in detail the technique of making these applications both in the home and in the hydrotherapeutic institution

Among the great variety of methods that should be available in the patient's own home the author enumerates (1) the half-minute bath with frictions, (2) the very brief cold shower with frictions, (3) the cold pack with wrung-out cloths, the cloth being constantly rubbed to and fro upon the skin, (4) the pack with waterproof cover, for sedation and transpiration, (5) the half-bath of Winternitz with affusion and friction, (6) baths progressively cooled or heated, (7) footbaths with rising temperatures The frequency with which frictions are enjoined is noteworthy Adjuncts include thermo-resinous baths for rheumatic subjects, with profuse perspirations and copious water-drinking The chief method at the establishment is the douche, which in its varied forms in France is admirably described—for example, cold, hot, alternating, with and without manipulation, general or localized to particular regions, precordial, hepatic, lumbar, plantar, etc

A final section of the book gives in full detail the indications and contraindications of hydrotherapy in a variety of cases The use of baths in fevers is carefully defined, a wide range is given for nervous diseases, forms of paralysis, neuroses, psychoses, Graves's disease, etc The applications proper in cardiovascular, dyspeptic, and rheumatic cases are fully detailed, and the directions given for treating these varied conditions are practical and precise The book itself is interesting and well arranged, and should serve as a sufficient guide to any medical man proposing to employ hydropathic methods in his own practice

HEALTH OF CHILDREN IN THE TROPICS

IN *The Care of Children in the Tropics*,[5] DR ERIC C SPAAR has provided a manual which should be of great value to the mother faced with the problems of a hot country The difficulties of feeding, clothing, and general management take on such a different complexion in the Tropics that the usual textbooks on child care either do not apply or are definitely misleading, and it is precisely to the points on which advice intended for temperate countries proves fallacious that DR SPAAR has paid most attention The book is divided into three sections, of which the first is concerned with the general management of the infant, the second with modern methods of artificial feeding, and the third with the care of the sick child The importance of breast-feeding is emphasized, not only on physiological grounds, but because it affords the best chance of avoiding the enteritic infections which so often prove fatal to children in the East The points to be observed in choosing a wet-nurse, and those on which an ayah requires close supervision, are set out in detail, and the chapters on artificial feeding have been made extremely clear and straightforward The difficulties of obtaining clean cow's milk can only be surmounted, DR SPAAR finds, by buying the cow The final chapters on common ailments, though they should be an excellent guide to a sensible mother, may conceivably have the opposite effect on the nervous type, who, learning for the first time that headache may mean meningitis, and distended abdomen peritonitis, will weary the overworked doctor with false alarms There can be no doubt, however, that the book successfully meets a need felt alike by the mother and the medical practitioner in the Tropics

NOTES ON BOOKS

THE second edition of *Recent Advances in Diseases of Children*,[6] by DRS W J PEARSON and W G WYLLIE, appears less than two years after the first, and although "advances" in this branch of medicine have certainly occurred during the interval the changes in the text are more extensive than mere bringing up to date will account for The "acid" and "alkaline" children of the first edition have undergone some modification into "neuro-arthritic" and "lymphatic" respectively, and, indeed, all the chemistry of the book has been carefully revised and loose terminology deleted From the preface it may be deduced that this is largely due to "helpful criticism" by DR G A HARRISON Sections on encephalitis, on chest conditions, including asthma, and on skin tests have been considerably altered and brought up to date, while changes also appear in the sections dealing with chronic infection of the tonsils and adenoids, chronic abdominal conditions, and on congenital syphilis DRS PEARSON and WYLLIE acknowledge that they have purposely been provocative in this work, which still remains more a textbook than a mere record of recent advances While there is much less cause for direct criticism in this second edition it still contains a great deal of material which is novel by reason of the authors' approach to the subject, and the book as a whole gives considerable food for thought.

The second edition of the *Slit-lamp Microscopy of the Living Eye*,[7] by DR KOBY, which is translated by MR CHARLES GOULDEN and MRS HARRIS, is considerably enlarged and improved in comparison with the first The general arrangement of the text is preserved, but it has been amplified by inclusion of the very large mass of new observations which have been recorded since the book first appeared five years ago The thoroughness with which DR KOBY keeps abreast of current literature in this ever-enlarging field of clinical ophthalmological practice is no small achievement, and the value of his book is enhanced by his own observations and by the lucid expression of his own criticism or appreciation of the work of others The number of illustrations has also increased very considerably, and although they fall short of the beauty of those found in the German atlases they are not lacking in clarity, and are all the more valuable in that the vast majority of them come from the author's own hand The present volume is an already very useful book considerably improved

[6] *Recent Advances in Diseases of Children* By Wilfred J Pearson, D S O, M C, D M, F R C P, and W G Wyllie, M D, M R C P Second edition London J and A Churchill 1930 (5½ × 8½, pp x + 584; 34 figures, 20 plates. 15s)

[7] *Slit-lamp Microscopy of the Living Eye* By Dr F Ed Koby Translated by Charles Goulden, O B E, F R C S, and Clara Lomas Harris, M B Second edition London J and A Churchill 1930 (Demy 8vo, pp xvi + 360, 104 figures 15s)

PREPARATIONS AND APPLIANCES

APPARATUS FOR INTRAVENOUS TRANSFUSION

THE Crookes Laboratories have prepared a series of solutions suitable for intravenous transfusions, each put up in a special glass container and ready for use in emergency The containers, as will be seen from the accompanying illustration, are ampoule shaped, and have at one end an air inlet to which an air filter can be fitted by means of a short rubber tube, and at the other an outlet tube which, when the apparatus is required for use, is connected to a cannula The standard aseptic solutions at present available are gum saline, hypertonic saline, normal saline solution, and normal glucose The transfusion ampoule is supported in a metallic holder, so designed that it can be suspended over the patient's bed or near the operating table A small pamphlet giving full particulars may be obtained on application to Crookes Laboratories (22, Chenies Street, London, W C 1)

SUMMARY OF PROCEEDINGS

(Concluded from page 517)

SECTION OF OBSTETRICS AND GYNAECOLOGY

Friday, August 29th

THE PLACENTAL HORMONE.

THERE were 229 present when, under the chairmanship of Mr CONYNS BERKELEY, a paper entitled "The placental hormone 'emmenine'" was read by Professor J B COLLIP (Montreal). In summarizing his work in the *Canadian Medical Association Journal* (1930, xxii, 761) he had he said, drawn the following conclusions. There were three distinct active principles or hormones in the placenta which were alike, in that they had all been observed to be oestrogenic in the immature female rat. "Emmenine" was the active principle in the second fraction (85 per cent alcohol soluble), and was very similar to oestrin in its ultimate physiological effects. It was ineffective however, in the castrate, and hence it might be concluded that it functioned directly or indirectly by stimulation of the intact ovary. Also it differed from oestrin in the degree to which it was effective by oral administration. The third fraction, prepared from the alcohol insoluble material of the original extract, was similar to the other two in that it was oestrogenic, but differed from the "emmenine" fraction on three points: (1) it was ineffective by the oral route; (2) it produced corpora lutea in the immature rat coincident with induced oestrus; (3) it caused an increase in the rate of growth of the accessory sex glands in the immature male. As yet he had been unable to obtain with certainty any of the above fractions other than oestrin from pig and cow placenta, and this observation, which must be studied further, suggested that in the human placenta hormones existed which were absent in the lower mammals. This suggestion received support from the observation that pregnancy urine of certain of the lower mammals has failed to give an Aschheim Zondek reaction when injected into immature mice. He considered the two oestrogenic placental hormones other than oestrin ("theelin") to be the counterparts in placenta of the "prolan A" (oestrogenic) and "prolan B" (oestrogenic and luteinizing) of urine described by Zondek and Aschheim. He was also of the opinion that these active principles were the specific products of placental tissue functioning and were actively related to the condition of pregnancy. Much more research was necessary before we could correlate the functional interrelationship between the pituitary sex hormones and those of the placenta.

Mr CONYNS BERKELEY having drawn the attention of the meeting to the profound biological researches of Dr Collip particularly in connexion with the establishment of a workable manufacturing process for the isolation of insulin and the parathyroid hormone, said that this new work in the field of sex hormones was a great advance and would be of immense value when the results could be accurately interpreted. Dr A D CAMPBELL (Montreal) related a series of cases in which "emmenine" had been given therapeutically in various derangements of menstruation. He considered that the periodicity of menstruation was due to a hormone released from the anterior pituitary gland, but that alterations were usually due to ovarian derangements. He found that 'emmenine' did not disturb the normal menstrual cycle, that its exhibition in cases of primary and secondary amenorrhoea had little effect, but that in epimenorrhagia the intervals were appreciably lengthened. The best results were obtained in cases of dysmenorrhoea which were nearly always relieved, but the effect was not permanent and on discontinuing the administration the symptom recurred. He had never found that abortion was brought about when the hormone was administered to a pregnant woman. Professor W W CHIPMAN (Montreal) said that while this was only a preliminary report on the work of production and use of "emmenine" the results were so far satisfactory and should stimulate further investigation. He said that the placenta, which was really an ovarian tissue, and the ovum were dependent on one another and probably the placenta was the storing-ground for ovarian hormones and not the site of origin of specific hormones. Professor V J HARDING (Toronto) said that much confusion had arisen from the multiplicity of hormones present in the ovaries, and that he was struck by the fact that extracts of "emmenine" had no deleterious effects in contradistinction to the results from overdosage with other endocrines, this was probably because 'emmenine' acted as a sort of pre-oestrin stimulating the production of oestrin. He had found improvement in cases of vomiting of pregnancy by the administration of "emmenine."

TREATMENT OF PROLAPSE.

Mr T G STEVENS (London) then gave a very clear demonstration on the operative treatment of prolapse, defining the principles and technique he had used in the treatment of 1,800 cases. This closely followed the teachings of Donald and Fothergill of Manchester but in the anterior colporrhaphy he made a vertical mid line incision and carefully dissected the bladder from the cervix, which was supported by mattress sutures inserted in the parametrium. He considered that amputation of the cervix was performed far too frequently, and he only carried out this part of the Manchester operation when there was marked hypertrophy or mobility of the cervix. He only added a laparotomy when there was a persistence of symptoms, or retroflexion or some abdominal complication associated with the prolapse. He treated the rectocele by a straightforward posterior colporrhaphy, commencing at the top of the vagina, and never considered it necessary to open the pouch of Douglas to treat the hernia occurring here. The operation was discussed, with general agreement on the main principles by Mr CONYNS BERKELEY, Mr C D LOCHRANE (Derby), and Professor JOHN FRASER (Montreal). Mr Lochrane said that he did not find it necessary to separate and dislocate the bladder upwards in most cases and that this procedure was called for only when a relatively high amputation of the cervix was needed, in cases of definite cystocele without much descent of the uterus, and in a majority of post-menopausal cases in which the corpus uteri was markedly retroverted and bulky. In cases of the latter type the procedure was helpful in allowing the suture of the lower part of the corpus uteri to the anterior vaginal wall to maintain the uterus in an anteverted position.

ANAESTHESIA AND ANALGESIA IN CHILD-BEARING.

The concluding discussion of a long session was opened by Dame LOUISE MCILROY, who, in the course of her remarks on the position of anaesthesia and analgesia in child bearing said that there was much interest in the subject at present in England. Public discussions were taking place and funds were being raised for the establishment of special resident anaesthetists in the maternity departments of the large hospitals. The medical profession was anxious to relieve suffering, but painless labour could not be achieved artificially without some risk to the mother and more especially to the child. Anaesthetics were always given in maternity operations and as a rule in complicated deliveries, but the medical profession had to solve the problem, How far with safety could freedom from pain be procured? Much more could be done to relieve pain than had been done hitherto. If every woman was to have anaesthetics this would involve longer attendance by the medical practitioner and therefore more expense. Skilled anaesthetists would be required to assist at the confinement. Anaesthetics tended to prolong labour, and there was much discussion on the most suitable drugs that should be employed as sedatives during the stages of labour, and the most suitable anaesthetic for delivery. The use of drugs diminished fear and shock and therefore was a factor in the reduction of maternal mortality. Operative intervention was also prevented by the use of analgesics as the patient and her relatives were not harassed by the sufferings of a prolonged labour. Turning to the actual consideration of the drug to be used she said that morphine in small doses was most beneficial, but had to be used with skill and caution as it might have a harmful effect upon the child. Morphine was frequently

combined with scopolamine In very few cases was twilight sleep fully induced in England, as it involved special skill and surroundings for its administration Chloral hydrate, with or without potassium bromide, was the favourite sedative in use It was safe and easy to give For the latter part of labour chloroform or ether was given at intervals, and deeper anaesthesia during delivery The majority of obstetricians preferred ether, but chloroform had many advocates Chloroform was unsafe in cases of toxaemia, such as eclampsia, or in heart disease Ether was irritating in its effect in cases of lung complications The safest and best anaesthetic was nitrous oxide gas and oxygen It, however, required to be given by a trained anaesthetist, and it necessitated carrying about cumbersome apparatus Various local and spinal analgesics were being employed, but opinions differed on the advantages and disadvantages of each The conclusions arrived at by Professor McIlroy were as follows Every maternity case must be given individual attention with regard to the most suitable sedative and anaesthetic to be employed The age, parity, temperament, general health, and complications all had to be carefully considered Obstetrical anaesthesia was not comparable with surgical The pain was prolonged, and had to be combated with sedatives as well as anaesthetics The effect of these sedatives had to be taken into consideration when an anaesthetic was decided upon Light anaesthesia was of little use in surgery, while it was generally employed in midwifery practice except in cases where operative intervention was required It was important that the action of the uterus should be maintained and haemorrhage after delivery prevented Time and cost were considerations Private patients should have the continuous attendance of the practitioner during labour if sedatives or anaesthetics were to be given, just as patients had in hospital practice, yet it was impossible to demand this unless adequate payment was made by the patients

SECTION OF SURGERY

Friday, August 29th

THE SYMPATHETIC NERVOUS SYSTEM

At its final session the Surgical Section considered various aspects of the physiology and the surgery of the sympathetic nervous system Dr W J MAYO (Rochester, Minnesota) opened the discussion by giving an historical account of the discovery of the anatomy and physiology of the sympathetic ganglia and rami, mentioning the contributions of Winslow, Petit, Haller, Remak, Muller, Claude Bernard, Gaskell, and the work of the Cambridge school He pointed out that the surgical approach to the sympathetic involved the wider problem of the relation of this system to the endocrine glands Dr Mayo was unwilling to admit that removal of a single adrenal gland caused any permanent disturbance in the physiology of the organism, and he therefore questioned the wisdom of such a procedure in patients suffering from high blood pressure In closing, he referred to the effect of ramisection on conditions such as arthritis, Raynaud's disease, and Buerger's syndrome, and asked whether coronary disease might not be an end-result of a similar vasospastic process, and whether early sympathectomy might not prevent the onset of angina pectoris and allied disturbances

Dr N D ROYLE (Sydney, N S W) then followed with a paper entitled "The clinical results following the operation of sympathetic ramisection," in which he stated that he had performed the operation six hundred times with a mortality rate of 0 5 per cent —that is, with three deaths The operation was introduced by him originally in 1923 for the treatment of spastic paralysis, and, excluding extrapyramidal conditions 70 per cent of the patients so treated had been distinctly benefited A large proportion of them had been followed carefully and end-results were summarized More recently Dr Royle had used the operation experimentally for treatment of the following conditions Parkinsonian rigidity (results poor), Hirschsprung's disease (results excellent in all cases), sarcoma of [illegible] (relief of pain), Raynaud's and Buerger's [illegible] gratifying, but better in the former condition), writer's cramp (one case, relief), poliomyelitis (results poor) conditions simulating tic douloureux (one case), retinitis pigmentosa (five cases, recovery of vision following extirpation of thoracic sympathetic) The most important new development related to Dr Royle's discovery that retinitis pigmentosa responded to sympathectomy to a degree that caused the recovery of 20/30 vision in one patient whose visual acuity had previously been reduced to shadow perception Dr Royle still enthusiastically favoured the operation of ramisection in cases of spastic paralysis

Dr J F FULTON (Oxford), who discussed the physiological basis of the surgery of the sympathetic system, described first the relation of this system to the general physiology of the organism, mentioning Claude Bernard's prediction that regulation of the internal activities of the animal body was carried out by the nervous system, and alluding to the recent discovery that the centres of the autonomic system lie in the hypothalamus (Beattie and Long and their co-workers) In discussing the mechanism of postural responses Dr Fulton pointed out that the stretch reflex, which was at the basis of posture, was not abolished by sympathectomy, though the transient diminution in rigidity occurring in spastic cases after ramisection suggested that the operation might cause an increase in threshold for eliciting the stretch reflex From the physiological point of view justification for the employment of ramisection in cases of hypertonia was an open question The operation of periarterial sympathectomy was without anatomical or physiological foundation There were no long vaso-constrictor fibres passing distally in the larger arteries The operation might, however, be useful for the relief of intractable pain Apart from certain visceral conditions, such as Hirschsprung's disease, the only clear-cut indication for sympathectomy was ischaemia Any pathological process in which healing would be greatly accelerated by an increased blood supply offered an indication for ramisection, especially if the morbid process threatened the existence of an extremity Since collateral circulation in a limb was established more readily after ramisection than with vaso-constrictors intact, an extremity in gangrene from thrombosis should not be amputated without first giving it the benefit of ramisection It was emphasized that conditions improved by sympathectomy were not due necessarily to hyperactivity of the sympathetic

Dr J R LEARMONTH (Rochester, Minnesota) emphasized that the action of both parasympathetic and sympathetic nerves upon the bowel and bladder should be regarded as a means of harmonizing an important physiological necessity —the disposal of the waste products of the body Operations upon the sympathetic nerves of the bowel were indicated in cases of nervous imbalance, such as Hirschsprung's disease, and constipation due to dulling of the defaecation reflex He described a new operation by which the whole sympathetic nerve supply to the lower colon, the rectum, and the internal anal sphincter could be interrupted, with preservation of the vasomotor nerves to the limbs In the case of the bladder, he described two cases in which defective micturition, due to lesions affecting the parasympathetic pathway, had been rectified by division of the sympathetic nerves to the bladder, and advanced the hypothesis that these nerves might mediate an inhibitory action on the musculature of the human bladder He also described cases of vesical dysfunction which had been benefited by removal of agents compressing the dural sac under a lumbar or sacral spina bifida occulta The operation of total denervation of the bladder was also referred to and the indications for performing it were discussed

Dr R B WADE (Sydney, N S W) gave a commendably critical report of progress concerning the treatment of Hirschsprung's disease He had carried out left-sided lumbar ramisections for this condition in fourteen cases, and had had striking improvement in all but one, with the establishment of regular bowel movements and normal control of the anal sphincter The unsuccessful case responded temporarily, however, when the rami on the right side also were sectioned The unilateral operation

had been employed in many cases of chronic constipation with satisfying results

Dr WILDER PENFIELD (Montreal) in a paper entitled "Vascular changes observed in the brain during epileptiform seizures" mentioned at the outset that he had been able to demonstrate small medullated nerve fibres supplying a large proportion of the cerebral blood vessels, three cases of epilepsy were then described in which during exposure of the brain under local anæsthesia sharply circumscribed areas of anæmia appeared at several points in and about the motor area in the course of several carefully studied focal seizures. In the second case one of the recorded seizures consisted merely of clonic twitching of the eyelids and turning of the eyes to the right and the seizure was accompanied with an isolated area of chalky pallor in an area corresponding to the frontal eye field. In some circumstances the larger cerebral arteries were seen at several points to constrict sharply, giving a beaded appearance to the whole vessel. Dr Penfield concluded that since stimulation of the sympathetic nerve caused such extreme vasomotor activity the cerebral vessels must receive some innervation other than the sympathetic and therefore that surgical extirpation of the sympathetic in epilepsy was of doubtful value.

Dr A. W. ADSON (Rochester, Minnesota) who dealt with indications for, and the therapeutic value of, sympathetic ganglionectomy and trunk resection in the treatment of peripheral vascular diseases, mentioned the two existing theories concerning the origin of Raynaud's disease, one upheld by Lewis who maintained that the vascular spasm was due to a purely local condition in the tissues affected, while Dr Adson and others contended that the disease resulted from hyperactivity of vaso-constrictor reflexes and that the fault therefore lay in the central nervous system. The speaker pointed out that in his cases after complete removal of the vaso-constrictors supplying the lower limb, it was impossible to evoke vasomotor spasm, however intense the stimulus. The occasional persistence of spasm in the upper extremities was attributed to failure to remove all fibres. The more favourable results from the radical procedure recently introduced for the upper extremity supported this inference. At the Mayo Clinic the suitability of a case for operation was determined by a "vasomotor index"—that is, the ratio of the rise of temperature in the extremities to that in the mouth in fever produced by injection of typhoid vaccine. Dr Adson had also proved that retinal arteries dilated after thorico-cervical ramisection. In concluding he showed his first case of Raynaud's disease operated on five years ago which had remained free from symptoms during that period, and also a case of Buerger's disease in which the morbid process had been successfully arrested in the upper extremities two years previously.

At the end of the discussion Lord MOYNIHAN read a paper by S. H. HARRIS and R. C. S. HARRIS of the urological department of the Lewisham Hospital, Sydney on renal sympathicotonus and renal sympathectomy. This operation was introduced in the hope of relieving certain obscure cases of persistent renal pain. Details were given of the nerve supply of the kidney, the operative technique for denervation of the kidney, and the indications for the new procedure. Pain associated with delayed emptying of the renal calyces and pelvis together with dilatation of the pelvis constituted the chief positive signs. The writers *proposed to consider* at a later time the relation of this operation to nephritis and essential hæmaturia.

In the discussion which followed Dr ROBERTSON (Toronto) described a case of spastic paralysis operated on in his clinic by Dr Royle three years ago in which the result was distinctly favourable and had remained so. He also mentioned several cases of arthritis and of Hirschsprung's disease which had been successfully treated by ramisection. Dr FLOTHOW (Seattle) said that he had seen Dr Royle's cases in Australia and could confirm his claims. He then described a case in which some months after lumbar ramisection a cervical ganglionectomy was performed, and during the general hyperthermia (108° F.) which followed, the lower extremity, whose lumbar sympathetic chain had been removed, showed evidence of extreme vaso-constriction. In a happy speech Lord MOYNIHAN drew attention to the high level of the discussion and pointed out its relationship to the development of surgery in the past fifty years. Following upon the revolution effected by the work of Lister, surgeons had concerned themselves with the restoration of mechanical disorders by mechanical means. Surgery was now entering an era which might aptly be termed an era of physiological repair. The divorce of physiology and anatomy that supervened at the close of the career of Sharpey had been unfortunate, and its ill effects had persisted up to the present time. Lord Moynihan, however, seemed to discern the restoring hand of the surgeon. The synthetic action of surgeons, begun by Dr Royle was bringing physiology and anatomy together again, not by means of animal physiology but by means of human physiology. The inaugural symptoms of disease should be studied by those who were conversant with normal physiology rather than with the pathology of the post-mortem room. For the philosopher this was the lesson offered by the day's meeting.

SECTIONS OF MENTAL DISEASES AND NEUROLOGY AND MEDICINE.

Friday, August 29th

ACUTE POLIOMYELITIS

LORD DAWSON OF PENN, President of the Section of Medicine acting as chairman, took the opportunity, as it was the last meeting of the Sections, of thanking all officers for their untiring efforts in making the meetings the success they had undoubtedly been. Sir FARQUHAR BUZZARD in opening the discussion, considered it fitting that the subject of acute poliomyelitis should be discussed in Canada, not only because the Dominion had been visited by severe epidemics of the disease, but because its public health authorities and medical profession had compared very favourably with those of other countries in the enlightened and progressive policy for combating the disease. Referring to epidemics of recent years and the work that had been done in dealing with the situation, he concluded that there was little doubt that, in the organized employment of serum therapy, a definite forward step in communal preventive medicine had been made, and that as a result many limbs and lives had been saved. For a number of years it had been held that the virus of poliomyelitis entered the central nervous system from the respiratory mucosa via the perineural lymphatics, as in tetanus, rabies, and diphtheria, and that it reached the grey matter to set up an acute inflammation of the intertitial tissues. This mode of spread, it was thought, would explain both the pathology and the clinical course of the disease. Recent research on experimental animals by Fairbrother and Hurst tended, however, to disprove this theory and suggested that the axis cylinders were the chief routes or transmission of the infective agent. Before accepting this revolutionary doctrine as applicable to human poliomyelitis the speaker felt that further critical examination was necessary, as the theory did not fall in line with the anatomical and symptomatic features of the illness as they were known. The question was more of academic than of practical importance however and there were many others more urgently needing solution. One of these the speaker thought to be the possible modes of propagation in the community. Direct contact and spread by respiratory droplet infection was accepted as a possible though uncommon mode of transmission but that carriers were largely responsible for epidemics was more likely. Until we had more practical methods of testing and distinguishing between natural and acquired immunity, the problem was not likely to be solved. There was no doubt that immunity was frequently acquired by the response to infection with the virus without affection of the nervous system and it was impossible with our present knowledge to estimate the activity of such carriers in spreading infection. The chief methods of propagation were contact with acute cases, healthy or unhealthy carriers, and occasionally foods such as milk. The hypothesis that some of

the obscure febrile illnesses of children were really attacks of poliomyelitis, and that increasing immunity among adults could be so explained, had not been proved, but it was pointed out that if a test for the virus in all cases of pyrexia of unknown origin could be established, the first step towards the truth would have been made According to Collier, epidemics of poliomyelitis were preceded by "carrier epidemics," and, in congested communities, acute cases of the disease developed rapidly about the same time, having all been infected by carriers If this was correct, there would be little need for isolating acute cases of the disease However, there was not general agreement on this subject, and certainly not sufficient evidence to justify the exposure of healthy children to others suffering from the disease Detection and control of the "carrier" would appear to be the most important step in preventing epidemics, but when the present status of prophylaxis and treatment was reviewed, we were faced with so many doubtful and misleading factors that no dogmatic statement could be made, further progress would depend on advances in knowledge of the virus There was still some doubt as to the causative agent in spite of the apparently successful attempt by Flexner and Noguchi to cultivate specific globoid bodies The absence of a specific test for recognizing early and abortive cases made this gap in our knowledge a serious obstacle to accurate statistics The importance of the use of convalescent serum could not be overestimated, but who could predict what would have happened in the absence of such therapy? Other methods of treating acute poliomyelitis had been tried with no more positive results, and one was forced to the conclusion that further advance could not be made until a biological test ensuring early diagnosis had been discovered For this purpose the speaker suggested that an exhaustive study of all pyrexias of unknown cause in children would be necessary In conclusion, he mentioned the period of separation as the one in which the orthopaedists of late years had minimized the tragic disablement of infantile paralysis and it was, he thought, one of the brightest chapters in the recent history of the disease

Prof H B CUSHING (Montreal) followed by giving an historical sketch of epidemics in Canada and the development of convalescent serum therapy The efficacy of the latter he felt had been positively proved by the following arguments in its favour (1) it was analogous to serum treatment in other diseases, (2) in animal experimentation it had been shown that small doses of the serum produced immunity to large doses of the virus, and (3) it had withstood the clinical test It had, however, the following limitations (1) satisfactory immunity was of short duration (2) serum was effective only in the pre-paralytic stage (3) serum being ahuman, was difficult to obtain in sufficient quantity During epidemics, health departments in Canada had found communities anxious to co-operate At Montreal, during the past epidemic, cripples for miles round had written to the health department offering to come at their own expense to supply serum, if required In concluding, the speaker said that he held no special brief for convalescent serum, but he would like to impress on health authorities the extreme importance of always having on hand a sufficient supply to meet any possible emergency At this time Lord Dawson of Penn vacated the chair to Dr Edmund I Spriggs (North Wales), Vice President of the Section of Medicine Dr J M MCLACHLIN (Winnipeg), following, stated that it was his privilege to speak on behalf of the Medical Research Committee of the University of Manitoba, and therefore on behalf of a large number of workers who, under the able leadership of Professor C R Gilmour, had made a special study of the Manitoba epidemic in that province in 1928 Possibly the most important results to be presented were those obtained by convalescent serum therapy The method was not new and the evidence in its favour was not conclusive but since it was for the first time used extensively in Canada in the 1928 epidemic, the results had come to attention Over 8,000 cases of the disease had been treated under the direction of Professor C T Hagan Convalescent serum used during the Manitoba epidemic was the particular method of administration was used by them It had been the committee's experience that the serum was practically useless except in the pre-paralytic stage, hence the importance of being able to recognize the prodromal symptoms of the disease Of the 435 cases recorded during the epidemic, 161 had been selected for the purpose of estimating the value of serum therapy The basis of selection had been (1) a positive diagnosis, and (2) the accuracy and completeness of records obtained The series had been divided into the following groups (1) cases which received one dose of serum intramuscularly in the pre-paralytic stage, (2) those which received two or more doses by various routes in the pre-paralytic stage, (3) those which received serum after the onset of paralysis, and (4) those which received no serum The following table, which was shown on the screen, illustrates the outcome in each group

Group	No of Cases	Completely Recovered		Residual Paralysis		Deaths	
		Number	Percent	Number	Percent	Number	Percent
1	57	53	93	4	7	0	0
2	17	16	94	1	6	0	0
3	33	7	22	15	45	11	33
4	54	14	26	34	63	6	11

In concluding, the speaker stated that the committee, as a result of its work, was convinced of the value of convalescent serum in poliomyelitis Dr GEORGE RIDDOCH (London), following, said that his whole interest in the discussion centred around the research work done in Canada and the use of convalescent serum He was convinced that it should be employed more extensively in Great Britain He agreed with Sir Farquhar Buzzard that isolation of the causal agent was most important Dr ALEXANDER GIBSON (Winnipeg), speaking for the orthopaedic division, followed by saying that there was no work more gratifying than that of reparation in cases of poliomyelitis These cases illustrated the necessity for co-operation between the different specialties, specialists were too prone to confine their interests in watertight compartments The discussion, so far, had centred round the acute phase of the illness, and from what he had heard the speaker concluded that if serum were more extensively used the work of the orthopaedist would be much lessened No one knew to what extent recovery might occur, but it was the duty of the orthopaedist, after the acute phase had passed, to prevent distortion Massage and electrical treatment should not be prescribed, muscles were best left alone, except for the stimulation of "skin stroking" After outlining briefly orthopaedic measures for preventing contracture of muscles, the speaker concluded by saying that the more that was accomplished by those working on the problems of immunity, the less there would be for the orthopaedists to do Dr R G ARMOUR (Toronto) said that an aspect of the disease which had always impressed him as important was the frequency with which gastro-intestinal symptoms occurred during the pre-paralytic stage He referred to a series of cases studied by him in New York in 1911 It had been noted in this study that where a large dose of castor oil had been administered early in the disease the acute phase was never so severe, and the sequelae never so serious, as in cases not so treated From this he concluded that any case of diarrhoea and vomiting might be a case of poliomyelitis, and that castor oil should always be given Another therapeutic measure which had not been mentioned was rest during the acute stage Absolute rest during this period tended to lessen the spread of congestion in the spinal cord, and thus lessen the severity of sequelae During poliomyelitis epidemics it was noteworthy that there were always a number of illnesses diagnosed as intestinal influenza Might not these be cases of poliomyelitis in which there was no paralysis? Sir FARQUHAR BUZZARD, in replying, complimented the Sections on the fruitfulness of the discussion, and stated that he agreed with all that had been said He wished to emphasize the importance of Professor Cushing's statements about the

need for health departments always to be forearmed He was much interested in Dr Gibson's remarks, and agreed with his views regarding the ill effects of massage and electrical treatment on sequelae He thought that swimming should be more universally employed as a remedial measure and referred to the good results obtained by swimming exercises for a group of paralytics which he had had under his care during the war He agreed with Dr Armour that gastro-intestinal disturbances were common but not universal The transportation of poliomyelitis cases during the acute stage was extremely dangerous, and he agreed with the speakers who had stressed the importance of rest during the acute stage of the disease

SECTION OF DISEASES OF CHILDREN

Friday August 29th

DISORDERS OF SLEEP IN CHILDHOOD

WITH DR ROBERT HUTCHISON in the chair, DR HECTOR CAMERON (London) opened a discussion on disorders of sleep by remarking that no more was known of the physiology than of the pathology of this condition and therefore up to the present clinical observation had been the only help to the study of the subject He dealt with four types (1) sleeplessness and continuous crying in young infants, (2) sleeplessness in older children, (3) night terrors, and (4) nocturnal enuresis In the first type he considered that there were three factors—pain, inherited neuropathy, and faulty management Among common causes of pain, most of them well known, he included aerophagy, which interfered with suction action, produced unrest and discomfort with a minimal food intake, and so led to the establishment of a vicious circle "To prevent wind we must secure sleep, and to secure sleep we must prevent wind" He advocated the use of chloral hydrate in one-grain doses, given before feeds, in these cases of unrest Two common causes of failure of lactation and consequent sleeplessness were nervous unrest and nasal obstruction Dr Cameron painted a vivid picture of the infant with a neuropathic inheritance, but went on to say that only a few babies suffered from this, a more frequent fault was bad management on the part of the nurse or mother He stressed the exaggerated psychical stimulus which passed from the over anxious mother, and referred to the sensible arrangement by which the Indian squaw carried her baby on her back and went on with her work In older children sleeplessness was also very often a nervous reaction to the mother, refusal of food had the same origin The child should never be urged to go to sleep, but should be encouraged by the natural assumption that it would succeed. Sleeplessness might be transitory but if encouraged by maternal fears would be erected into a formidable habit These observations did not exclude the necessity of inquiring into such practical points as warmth, adequate ventilation, excessive fatigue, and lack of exercise Insomnia peculiar to children often evidenced itself by two particular symptoms—namely, night terrors and enuresis The metabolism of children was less stable than that of later life, in the nervous child especially a slightly abnormal biochemical reaction might be provocative of the severest symptoms In children the carbohydrate reserve was more easily exhausted The blood sugar fell and ketones accumulated in the blood The speaker described the symptoms of a child with ketonaemia including confused dreams and night terrors Enuresis was a specific night terror, and generally affected the child who was particularly sensitive about such matters He had often found that night terrors could be controlled by the administration of glucose DR R F ROBERTS (Winnipeg) limited himself to the clinical manifestations of sleeplessness during infancy Sleep in the young child was profound, so that it was undisturbed by the ordinary activities of a household The child should not be too much shielded from noise, or it would soon come to demand these conditions for ordinary sleep The dressing bathing, and feeding of young infants produced enough fatigue to be a factor in deep sleep The chief nursing difficulties were lack of an adequate sucking reflex and the impatient, awkward child such difficulties could be overcome by good management DR PORKE considered that constitutional tendencies played an important part in the disturbances of sleep He described the restless neuropathic infant and thought that this type of child generally lay on one side because of its tendency to head retraction it was easily disturbed by noise colic, or the contact of a soiled diaper, and required attention at frequent intervals during the night It always reacted in a pronounced way to digestive disturbances had frequent small stools with mucus and passed much gas This generally occurred during the first few weeks, and there was always a tendency to improvement as the child grew older It was necessary to reassure the mother since she often ascribed the symptoms to the poverty of her own milk She should be advised to take open air exercise and to cut down the fat and protein of her food When possible it was important to secure rest at night for the mother In case of severe colic the infant should be given castor oil and be kept on a diet of boiled water for eighteen hours If it was suspected that the infant was getting too much food, water or lime-water could be given before each nursing DR PORKE agreed that nasal obstruction was a common cause of failure in sucking and sleeping. He advised the use of paraffin and in many cases the early removal of adenoids He had not previously considered acidosis as a cause of sleeplessness Among other more obvious causes of sleeplessness he mentioned otitis media, acute infections, pyelitis eczema, and mental deficiency

DR A H SPOHN (Vancouver) said that sound sleep was an index of good health, pain and inherited neuropathy were the two important factors in sleeplessness Children had a relatively longer gut than adults and a thinner abdominal wall, so that they were more prone to dyspepsia He disagreed with Dr Cameron's theory of ketonaemia because he thought that night terrors were more marked after excessive carbohydrate ingestion In Canada and the United States the carbohydrate intake was in great excess, and there was also a high percentage of disturbed sleepers He considered the interference in carbohydrate metabolism referred to was rather a symptom than a cause Dr Spohn emphasized the inherited predisposition for disturbed sleep, and believed that it was becoming more common He did not think that nocturnal enuresis was a manifestation of hysteria, since it occurred when the patient was beyond the reach of hysterical influences, nor did he associate nocturnal enuresis with sleeplessness the former was common in institutional establishments, but the latter was rare In summing up the practical points of management he emphasized the necessity for considering eugenics, the readjustment of modes of living, and the establishment of a more normal home life He had used both atropine and luminal with some success and thought that hydrotherapeutic treatment was occasionally indicated DR ALAN BROWN (Toronto) suggested that thymus disease might be a cause of insomnia in some infants Children manifesting sleeplessness with some difficulty in breathing were occasionally found by x-ray examination to have enlargement of the thymus There might also be swelling of the nasal mucous membrane, which was supplied by a branch of the vagus He had seen six such cases, in which exposure of the thymic region to x rays produced relief and ability to breathe and sleep comfortably DR SWALLOW (Winnipeg) considered that one of the commonest causes of crying and restlessness in young infants was hunger DR RAWSON said that some cases of enuresis in childhood had been cured by distension of the bladder

ARTIFICIAL SUNLIGHT

DR ROBERT HUTCHISON announced that DR A. EIDINOW had been prevented from coming to Canada to speak in person DR ALAN BROWN (Toronto) had, however, consented to give the gist of DR EIDINOW'S paper and then to proceed with his own remarks on the subject DR EIDINOW'S paper referred in detail to the use of heat, infra-red luminous ray, and ultra-violet ray therapy in the treatment of disease Ultra-violet therapy might be employed for the normal skin for the irradiation of diseased parts such as ulcers, and for the irradiation of foods and

drugs The reaction of the skin depended on the intensity of radiation, character of wave-length, time of exposure, distance from the source of light, sensitivity of the skin, and area of skin exposed He described the methods of utilizing the long rays and the short rays He had himself designed a new lamp, the daylight lamp, with rays similar to natural sunlight Patients could be exposed for many hours, and could sleep under it without danger of skin reactions It consisted of a long mercury arc enclosed in a frosted vitreosil tube, and a series of tungsten filament lamps, easily controlled and foolproof Experiments showed that animals exposed to this lamp developed a greater power to withstand intravenous injections of staphylococci It should prove useful in convalescent states, but was contraindicated in all cases of acute pyrexial disease Dr Eidinow then described the various methods of short-ray therapy He said that pigmentation should be avoided, since this immunized the skin to ultra-violet rays The technique of short-ray therapy needed careful supervision, and was only safe in the hands of the specialist In 85 per cent of his cases the bactericidal power was increased on an average 7 per cent Dr ALAN BROWN said that Dr Eidinow's work conformed closely with that done in Canada, but that they had not much experience of local actinotherapy because there was very little lupus among children in that country Actinotherapy was not a form of treatment for all diseases, but it increased the resistance to disease He alluded to the experiments of Dr Robertson (Toronto), who had cultivated an organism of slight pathogenicity to rats, and had then produced in the rats by ultra-violet radiation a resistance to the organism 600 times greater than before In Toronto head colds had been very prevalent, and all forms of therapy had been tried, it was now the speaker's habit to administer long-ray therapy in November and February, and the results had been very beneficial Regarding the effect on digestion, it had been found that the hydrogen-ion concentration of faeces was increased in irradiated children, probably by the removal of buffer substances Dr Brown was convinced that sunshine was not used enough The active rays of the sun only became effective in Toronto in the first week of March, and lasted till the first week of October In winter the sun's rays were below an angle of 35 degrees with the axis of the earth, and were therefore useless The latitudes in which rickets occurred were those between 40 and 60 degrees It was important to remember the beneficial effect of "sky-shine"—the rays of the sun in the shade or through a film of cloud, these had as much as one-half to two-thirds of the value of direct sun rays Dr Brown recommended the use of foods with added vitamins in addition to the use of the direct ray Professor H B CUSHING (Montreal) said that the Alexandra Hospital for contagious diseases was nearly empty during July and August, he supposed this was due to the decreased virulence of organisms during the sunshine months, and the increased resistance of the children He hoped that eventually artificial sunlight would be provided in all schools, nurseries, etc Dr D NABARRO (London) spoke of the exposure of milk to actinic rays in the process of cooling Professor W E DIXON (Cambridge) disagreed with the former speakers, and said that human natural functions were not improved by adding excess of vitamin any more than by adding excess of any other food constituents Most living animals avoided excess of sunlight, and it was evident that the sun could do much harm He observed that with regard to the raising of an animal's resistance it had been shown that any substance injected into an animal raised its resistance One should not ignore the effect of irritation after exposure to rays or the psychical effect Dr MOORHEAD called attention to the fact that while advocating the use of vitamins most people preferred the bleached vegetables—notably celery, lettuce hearts, and asparagus Dr ROBERT HUTCHISON closing the discussion said that they had not heard enough of the contraindications for artificial sunlight, and little or no allusion had been made to the positive results of the experiments carried out under the auspices of the Medical Research Council He had noticed that in Canada they took precautions to exclude sunlight from their houses

SECTION OF ANAESTHESIA

Thursday, August 28th

POST-OPERATIVE RESPIRATORY COMPLICATIONS

At the second meeting of this Section Professor W WEBSTER, a Vice-President, occupied the chair Dr D C AIKENHEAD (Winnipeg) read a paper summarizing and commenting upon the post-operative respiratory complications in a series of 33,000 cases The paper is printed at page 515 of this issue of the *Journal*

The President, Dr R E APPERLY (London), congratulated Dr Aikenhead upon the magnitude of his figures Referring to his own experience, Dr Apperly stated that in twenty-two years he had administered over 37,000 anaesthetics to all types of patients He considered that the preliminary use of atropine had been largely responsible for the abolition of post-operative pneumonia, which nowadays was not so common as previously The routine practice in England was to give upwards of 1/100 grain of atropine, according to the age of the patient, this reduced the incidence of post-operative complications He had found that nose and throat operations were singularly free from respiratory complications, and he held the view that the inhalation of septic material was not the sole cause of such difficulties In pelvic cases he had observed almost as great freedom from post-operative respiratory complications, those which did occur usually followed radical hysterectomy These complications were noticed most frequently after operations upon the upper abdomen In such cases respiratory movement was restricted, which might be a factor He had found splanchnic anaesthesia valuable in these cases Dr Apperly added that there was no known routine method by which respiratory complications could be prevented, each case must be considered individually Dr LA FLECHE (Winnipeg) thought that lung complications should be styled "post-operative" rather than "post-anaesthetic", he considered the condition due to many factors, and especially to the pre-operative condition of the patient, preliminary medication, the site and region of the operation, the type of anaesthesia, the reduction of vital capacity, and the degree of post-operative care During an operation many of these circumstances tended to lower the patient's resistance The most important factors in prophylaxis were the use of CO_2 and oxygen to prevent atelectasis, and frequent changes of the patient's position in bed Dr FEATHERSTONE (Birmingham) stated that some years ago he had analysed forty different possible causes of post-operative respiratory complications, and concluded that the most prominent factors in their production were shock and infection, especially in operations upon the upper abdomen His impression was that post-operative pneumonia was not so frequent as it was ten years ago Possibly this was due to deficient nutrition consequent upon lung conditions Dr LAMB (Glasgow) said that some years ago he went through a series of post-mortem reports, and found no case of pure pneumonia as a post-operative complication, this was invariably associated with a septic condition He considered there was a great danger in operating upon patients with coryza, and he referred to the high incidence of abscess of the lung following tonsillectomy in America, as compared with its rarity in England Dr S JOHNSTON (Toronto) recalled a case of tonsillectomy followed by lung abscess in which the same culture was obtained from both sites In America tonsils were usually removed in the upright position, while recumbency was the rule in England Dr BOTSFORD (San Francisco) stressed the necessity of clearing up all throat infection before operating She believed that the nasal administration of gas and oxygen had largely reduced respiratory complications after tonsillectomy Professor W WEBSTER (Winnipeg) recommended the leaning forward position for tonsillectomy Anaesthesia should not be sufficiently deep to relax the soft palate, because in these circumstances blood and pus were inhaled This frequently happened when tonsillectomy was performed under local anaesthesia Dr F I McKESSON (Toledo, Ohio) considered that many factors predisposed to respiratory complications the most important was the depth of anaesthesia In tonsillectomy the patient should be kept lightly under, the airway should be free,

because any obstruction tended to cause congestion of the lungs Dr BLEZARD (Edmonton Alberta) said he had a great regard for atropine and gave 1/100 grain four-hourly after operation as a prophylactic Dr HAYES (Christchurch, New Zealand) stated that he had never seen a post-operative lung abscess in New Zealand Dr BIRKENHEAD replied to the questions raised in the discussion

SODIUM AMYTAL AS AN ANAESTHETIC

Dr L C ZERFAS (Indianapolis Indiana) read a paper dealing with the pharmacology and clinical applications of this drug a derivative of barbituric acid Dr J S LUNDY (Rochester, Minnesota) stated that he regarded 16 to 45 grains as an anaesthetic dose when given intravenously larger doses were toxic In some cases there had been post-operative excitement and he considered this due to the formation of isomers which had an entirely different action Sodium amytal should be regarded as an hypnotic rather than an anaesthetic The largest total dose he had seen administered was 9 000 grains, which had been given in individual doses, each of 3 grains for several months to check the convulsions of a patient with an intracranial tumour Sodium amytal was useful in the treatment of gastric and duodenal ulceration because it checked the secretion of the gastric juice Like all barbiturates it must be given with caution It was prone to cause oedema of the lungs, for which the best treatment was an oxygen tent and concentrated glucose solution intravenously Sodium amytal should not be employed in comatose conditions Dr BOTSFORD (San Francisco) described the effect of sodium amytal upon children She had employed this drug in a large number of cases and had noticed that, so far as children were concerned, the fear of operation was abolished with consequent diminution of the risk of causing subsequent mental complexes She administered the drug in capsules by the oral route, and obtained sleep or unconsciousness in five to twenty minutes She had seen no post-anaesthetic complications and had noticed no ratio between the lowering of blood pressure and the psychic effect She concluded that sodium amytal could be administered to children with safety, that it was more effective than opium in abolishing fear and that minimal doses should be given by the oral route Dr MOORE (Grand Forks, North Dakota) reported good effects in obstetrical work, particularly from its intramuscular administration Labour and even low forceps delivery could be conducted without the use of any other anaesthetic There was never any complaint of after-pains In reply to Dr FEATHERSTONE (Birmingham) he said that there was no untoward effect upon the child Dr BLEZARD (Edmonton) had employed the drug in obstetrics He stated that it relaxed the cervix Dr F B PARSONS (Cambridge) thought sodium amytal should be regarded as a particular form of premedication rather than as an anaesthetic With all non-volatile anaesthetics it was impossible to secure rapid absorption and excretion and therefore the anaesthetist could never be sure of his position, for these reasons inhalation anaesthesia was the more satisfactory He observed that there was considerable divergence in the recommended doses of sodium amytal this was an important point when dealing with derivatives of barbitone

Friday, August 29th

AVERTIN ANAESTHESIA

At the final meeting of this Section Dr H W FEATHERSTONE (Birmingham), Vice-President occupied the chair, and Dr F B PARSONS (Cambridge) read a paper on avertin He surveyed the field of non volatile anaesthetics in general, and discussed their disadvantages when compared with volatile anaesthetics especially in connexion with their absorption and excretion He described the pharmacological and anaesthetic properties of the drug stressing the importance of careful preparation of the solution Avertin had a marked effect upon respiration, this function was depressed with ordinary doses, while the cardiovascular system was uninfluenced In man both the duration and the depth of anaesthesia were subject to considerable variation and in no circumstances should the anaesthetist endeavour to produce full anaesthesia by increasing the recommended dose Anaesthesia could always be deepened by the subsequent administration of a volatile inhalation anaesthetic After discussing the absorption and excretion of the drug and its use in special conditions (particularly for patients suffering from exophthalmic goitre), Dr PARSONS said that the death rate intrinsic to avertin, after making all allowances for the submission of bad risks to operation, was about 3 in 10,000 This figure was comparable to that for chloroform, and he concluded that avertin was not an anaesthetic for general use when there were others, much safer, at our disposal Nevertheless in his opinion the drug was the best of the solid anaesthetics available at the present time, and it was of particular service in certain conditions

Dr J S LUNDY (Rochester, Minn.) stated that although the death rate for avertin for the first 30,000 cases was 3 in 10 000, this figure might conceivably be reduced considerably in the future He had ceased to administer avertin in aqueous solution, and now gave it in 6 per cent gum acacia Since adopting this practice he had seen no case of tender anus following administration Dr R WATERS (Madison) stated that he had used avertin intravenously In a very few minutes the patient was anaesthetized, but detoxication was rapid, and in approximately ten minutes the patient had regained consciousness The CHAIRMAN said his impression was that avertin was of considerable value for induction, and for this purpose it was the most pleasant anaesthetic we possessed In his opinion the ether test was too severe He preferred to give small doses of avertin During the recovery period the patient, although anaesthesia was light had muscular relaxation and it was necessary to watch the jaw He had had rectal irritation even when the solution had been most carefully prepared He asked if the solution of avertin in amylene hydrate deteriorated in the course of time Dr HAYES (New Zealand) asked what effect avertin had upon young children Dr S JOHNSTON (Toronto) questioned its value in nose and throat operations on account of the delayed return of the cough reflex He inquired if there was any appreciable fall in the blood pressure Dr BOTSFORD (San Francisco) felt that avertin was of less value than sodium amytal or other barbiturate preparations Patients did not regain their normal mental outlook for some days A disadvantage so far as America was concerned was that avertin could not be administered by a nurse Dr PARSONS in replying stated that avertin could be given to children provided the rules concerning dosage were observed There was very little fall in blood pressure during anaesthesia The solution in amylene hydrate was permanent

PRE-ANAESTHETIC HYPNOTICS

Dr F I MCKESSON (Toledo, Ohio) read portions of a paper with the above title On account of previous discussion on sodium amytal and avertin, he confined his remarks to pernocton Dr McKesson stated that pernocton was a complex synthetic barbiturate closely resembling sodium amytal It differed from the latter drug however, in that with hypnotic doses there was no fall in blood pressure The hypnotic power of pernocton was approximately twice that of sodium amytal, while the recovery period was half as long and was characterized by much less restlessness The drug was administered intravenously injection should be slow, otherwise the incidence of post anaesthetic sickness was increased Another distinct advantage was that only a small amount of solution had to be injected This was approximately 4 or 5 c.cm for the recommended dose was 1 c.cm for every thirty pounds of body weight In regard to pre-operative medication he said that he gave morphine 1/4 grain hyoscine 1/100 grain, and eactin 1/60 grain

Professor W WEBSTER (Winnipeg) remarked that nowadays a patient was given several drugs to produce anaesthesia He questioned the advisability of giving morphine then hyoscine then pernocton or avertin followed by nitrous oxide or ethylene and perhaps ether Dr R HANGRAVE (Toronto) asked if pernocton had any especial value in obstetrics, and the chairman, Dr H W FEATHERSTONE, inquired if the chemical composition of pernocton was similar to that of sodium amytal In reply, Dr MCKESSON

stated that we were using more and more drug in order to obtain balanced anæsthesia, and that better results were obtained with the "blunderbuss" method. He had had insufficient use of the drug in obstetrical work to give a considered opinion of its value. Pernocton had a close chemical relationship with sodium amytal. The President, Dr. R. E. MURPHY, said that the Section would wish to thank the Canadian officers for the excellent arrangement which had been made for the meeting. He also thanked them very much indeed for their wonderful hospitality. Dr. H. W. FEATHERSTONE endorsed the President's remarks. He referred to the coming centenary meeting of the Association, at which members of the Canadian Medical Association would receive a hearty welcome.

SECTION OF RADIOLOGY

Friday, August 29th

RADIATION THERAPY

THE second day's proceedings took the form of a discussion on different branches of radiation therapy, with Dr. A. J. BARCLAY, President of the Section, in the chair.

Professor GENDREAU (Montreal) outlined the recent progress made in the radiotherapy of cancer. He described a Coolidge tube which had been recently built to withstand 300 Kv. pulsating current at 3 Ma., and was now in daily use. High-tension generators capable of producing this current have been available for some time. He discussed how these highly penetrating *x* rays could be used with advantage. With a longer skin focal distance, higher filtration, and a larger field, it was possible to increase the dose at a depth. X rays could be used alone or in combination with radium, in those cases where extensive areas had to be homogeneously irradiated, and large quantities of radium were not available; it was of great advantage to combine *x* rays with radium. He stated that the rays of this new tube had a wave-length as short as the softer gamma rays of radio-active substances, and the intensity of radiation at any given moment was equal to that of 300 grams of radium.

Dr. DOUGLAS QUICK *then surveyed the general position as* regards the uses of radium in the treatment of cancer. He described the conditions in which radium could be employed with particular advantage, and laid stress on others in which it was only of value in certain phases of disease. There was no essential difference between the action of the salt and the emanation. The important thing was the particular method employed and the quantity of irradiation used. In certain circumstances he advocated the combination of operative surgery with radium and *x* rays. In describing the work which was being carried out in connexion with the more accurate estimation of dosage, he stated that the application of irradiation from a quantitative standpoint was largely dependent on the relative radio-sensitivity of a given tumour as determined histologically.

Professor JAMES EWING (New York), who followed, said that the new high-voltage *x*-ray machines described by Dr. Gendreau were a real triumph in physical research. There were some indications that the intermediate wave-lengths between *x* rays and radium might give therapeutic results not produced by any of the agents now available, but too much should not be expected. Moreover, the apparatus was very costly, *and it was well*, therefore, to look for other methods of intensifying the action of *x* rays, such as the use of toxic metals and bacterial poisons and elevation of temperature. Dr. Quick had emphasized the need for determining the dose necessary to destroy a given tumour, and then making sure that that dose was delivered. As a pathologist, said Dr. Ewing, he had been impressed with the importance of determining the nature of the tumours in the laboratory. It was essential to determine the degree of malignancy and the degree of radio-sensitivity of every variety of tumour that came under observation. It was not now possible to attain these results in every instance, yet progress was being made rapidly. In an apparently homogeneous group were found the widest variations in malignancy and radio-sensitivity, and unless these differences were known it was impossible to manage intelligently any form of treatment. Returning to the principle now adopted in determining the dose of radium and *x* rays, he said that there were some highly sensitive tumours which disappeared rapidly under radiation as a result mainly of direct killing of cancer cells. But there was a much larger group of relatively or extremely resistant tumours that could not be cured by killing cancer cells except by destructive doses, and with this group the principle of growth restraint by moderate repeated doses was probably much safer and more effective. It was essential that the radiologist should determine not only what type of tumour he had to deal with, but on what principle he would proceed in treating it. Dr. SEARS (Kansas City) laid stress on preventive treatment. He said that no situation had yet been conquered by cure. We must eliminate the cure. Radiation was like a small green.

Dr. MALCOLM DONALDSON (London) asked Dr. Quick whether he believed radon and radium had the same action provided the same amount of irradiation were given. In England great importance was paid to the time factor; perhaps we had become obsessed with the idea of a small dose for a long time. He asked Dr. Ewing whether he thought a neoplastic cell in a lymph gland was more resistant by virtue of its surroundings.

Professor GENDREAU, replying, said he had great hopes of rapid development of deep *x*-ray therapy. Dr. QUICK said that at the Memorial Hospital they were very much committed to prolonged irradiation. External radiation alone would not as a rule cure an adult form of carcinoma. He advocated a combination of treatments, both surface and interstitial. Dr. EWING, in reply, said he believed England was in a more favourable position as regards the fight against cancer than any other country. He thought that there were two forms of irradiation, direct and indirect action. In the low-growing adult cancers the cells were not killed by direct action.

TREATMENT OF UTERINE HÆMORRHAGE

Dr. MALCOLM DONALDSON emphasized the importance of radiotherapy in non-malignant conditions, especially those distressing attacks of irregular hæmorrhage so often associated with the onset of the menopause. He stressed the importance of excluding malignant disease. Either *x* rays or radium might be used in the treatment of these cases. If it was decided to give an anæsthetic to explore the uterus, then radium was the method of choice. On the other hand, in cases of pure menorrhagia, where malignant disease could easily be excluded, it was justifiable to use *x* rays, as this avoided an anæsthetic and enabled the patient to continue her work without lying up. Dr. Donaldson discussed the question whether an artificial menopause produced more severe symptoms than a natural one. He had found that in patients of 40 there was no difference.

Dr. F. W. PROUD (Vancouver), who followed, said he considered radium was specific in the treatment of hæmorrhagic diathesis in women. He drew attention to the fact that menorrhagia and metrorrhagia occurred at all ages. The young were most tractable *and sensitive*, the old were less so. Great care should be taken in the irradiation of patients below 20 years of age, as the ovarian function might become permanently impaired. For this reason *x* rays, because of its smaller dosage and greater margin of safety, was given at monthly intervals. In multiparæ, however, radium was the method of choice. In his work he used a dose of 1,800–2,000 milligram hours, and found that this dose was necessary to avoid recurrences. He laid stress on the sequels—necrosis and endometritis—but *pointed out that these could be controlled*. In treating the hard fibrous uterus the minimum dose should be given and repeated if necessary in three months. After this treatment about half the cases bled profusely once, and about one-third had two or more periods before becoming free. Diagnostic curettage was performed as a routine. In certain circumstances he advocated surgery, and in others a combination of radium and *x* rays. Dr. SHIPLEY (Saskatoon) suggested that an anæsthetic was not necessary for

the introduction of radium into the uterus He stated that he had found 300 milligram hours a sufficient dose to achieve the desired effect He suggested that the cessation of menstruation was brought about by some hormonal reaction of the endometrium Dr MALCOLM DONALD of stated in reply that as curettage was usually necessary he did not favour local anaesthesia He was surprised to hear that Dr Shepley was able to obtain complete amenorrhœa with a dosage of 300 milligram hours He believed the action of the radium to be on the ovaries primarily

RADIUM IN EPITHELIOMATA OF THE SKIN

Dr ROY WARD'S observations in opening this discussion are published in full in this issue at page 511

Dr HUGH MACKAY (Winnipeg), who followed, said he had had the pleasure of visiting the London Radium Institute and seeing Dr Roy Ward's work He congratulated him on his paper He considered radium was the method of choice in the treatment of basal-celled growths Cosmetically it gave good results, and it avoided the necessity of operation, and many elderly patients were thereby spared nervous shock He discussed the advisability of giving prophylactic doses to the primary lesion and to the glands after operation in cases of squamous epitheliomata Dr PROUD mentioned that he had been treating cases of rodent ulcer with a combination of x rays and radium, and Dr PIRIE spoke of his experiences in the treatment of rodent ulcer with x rays

Dr A F BARCLAY expressed the gratitude of the Section for the boundless hospitality it had received, and Drs PIRIE and MACMILLAN thanked the President and other members of the Section who had so kindly visited Canada for the meeting

SECTIONS OF PREVENTIVE MEDICINE AND TUBERCULOSIS

Friday, August 29th

PRIMITIVE RACES AND EPIDEMIOLOGY

THE members of both Sections met together, with Dr CHARLES PAPPITT (Calydon Sanatorium, Ontario), Vice-President in the chair, and considered during the first half of the session four papers upon the subject of primitive races and epidemiology

Professor S LYLE CUMMINS (Cardiff) opened with a paper on tuberculosis in African natives when brought into contact with civilization His attention had first been drawn to the subject by his experiences with the Egyptian Army between 1899 and 1909 Writing in 1912 he drew the conclusions 'that primitive tribes are highly susceptible to tuberculosis because, in the absence of the tubercle bacillus, they have never been obliged to protect themselves against the organism", and that civilized peoples are highly protected against tuberculosis because they have, in contact with the tubercle bacillus elaborated protective substances against this organism" European war experience led him to lay increasing stress on the individual acquisition of resistance through contact with infection Most of the acute tuberculosis on the Rand was due to the lighting up of old foci rather than to infection from without acquired for the first time in the course of mining work It was the young recruit arriving with "larval" or 'childhood" lesions still active in the glandular reservoirs that was in danger of acute generalization of infection, fatal within a few weeks when exposed to the combination of unfavourable physiological condition implied in the exchange of the native way of life for work in the mines and compounds of the Rand The lesions found were such as could be produced only by generalization through the blood stream from a preexisting lesion The facts of tuberculosis in Africans could best be explained by postulating that the race had not as yet developed inherited "immunity potential to the same extent as the white races Professor Cummins showed lantern slides contrasting the environment and ways of life of the natives (1) primitive in their natural surroundings (2) semi sophisticated from prolonged contact with the white races but living on their own lands, as in Portuguese East Africa, and (3) cooped up in the insanitary slums of modern industrial townships Later he dealt with the measures of prevention available The essential first steps consisted in affording to the natives in their territories conditions of life which ensured good nourishment and in the building up of a sound medical service

Dr J HARVEY PIRIE (Johannesburg) followed with some remarks on post-mortem findings in South African negroes The labour population was 400,000, there were 1,200 deaths from tuberculosis per annum, and five or six times that number were repatriated for tuberculosis In a study of 700 tuberculous individuals it was found that one-third had the disease complicated with silicosis These were practically all long-service men in the thirties and forties The two-thirds with uncomplicated tuberculosis were mostly short-service men in the early twenties The disease was acute and rapidly generalizing death was frequent within the first three months of service Invasion was overwhelmingly by the respiratory route There was a complete absence of bovine strains The post-mortem findings were those of generalized miliary tuberculosis, mostly with caseous bronchial or other gland mass At times the infection had tracked along the lymphatics from the thorax to the abdomen, or there was marked involvement of the serous sac, including the myocardium The liver and spleen frequently showed marked change, the kidneys rarely, bones and joints very rarely In the lungs a gelatinous pneumonia had been found, and in a few instances showed pulmonary tuberculosis

Professor J G FITZGERALD (Toronto), in a paper on laboratory evidence as an aid in early recognition of tuberculosis in contacts, directed attention to two laboratory procedures which he believed to be of value in epidemiological investigations of pulmonary tuberculosis —the tuberculo-complement fixation and inhibitive tests Caulfield and his collaborators in 1925, Norrvien and others, and recently Ogden had published the result of investigations Unpublished works by Ogden indicated that in a number of instances positive serological findings well in advance of the appearance of clinical changes made definite diagnosis possible much earlier than otherwise would have been the case Three to eight tests over a period of one to five years might be necessary The procedures were extremely complicated and could only be performed by skilled serologists Professor Fitzgerald described some encouraging results obtained at Toronto His paper gave references to the literature

Dr C H VROOMAN (Vancouver) presented a paper on the racial incidence of tuberculosis in British Columbia The population of British Columbia, some 600 000, was predominantly white but a group of about 70 000 consisted of Indians Japanese and Chinese in almost equal numbers The vital statistics of the province for the last nine years showed that this group comprising little over 10 per cent of the population was responsible for nearly 40 per cent of the total deaths from tuberculosis Among the white population 1 out of every 13 deaths was due to tuberculosis among the Japanese 1 out of every 6, among the Chinese 1 out of every 5, among the Indians 1 out of every 3 These very striking discrepancies raised the question of racial susceptibility to the disease The results of the physical examination of 1,248 individuals from selected groups of the 25,000 Indians of British Columbia including fishermen, agriculturists, and hunters were then described 6 per cent were found to be suffering from active tuberculosis, or 1 in 10 of the population if suspects were included The great majority of the attacks were of active fibro-caseous adult type showing little tendency to fibrosis, children between the ages of 5 and 14 were commonly affected Tuberculosis had not infected Indians for more than three or four generations As to the Japanese and Chinese it was probable that they too would show an incidence of tuberculosis proportional to their death rates Owing to their modes of life and lack of sanitary care the members of these three peoples were exposed especially in childhood, to more massive doses of tubercle bacilli than the white population

There was little time left for discussion of the papers Dr R G FERGUSON (Qu'Appelle, Sask.) said there was

little to be added to the known description of African conditions, but the report of the commission on silicosis was awaited with interest Work among the Indians was proceeding steadily in the pre-school, school, and reservation groups under whole-time physicians Dr A S M MACGREGOR (Glasgow) spoke of the incidence of tuberculosis among the Irish population of Glasgow, as compared with that of the indigenous population of the city Dr D A STEWART (Ninette) said that the medical problems of primitive races had been neglected Latterly the needs of the Indians, infected by the whites, were being realized A beginning had been made at Ninette among mixed strains of Indians long in association with the whites—a population permeated with tuberculosis and living under very bad conditions Raising of the standard of living and the practice of rational pursuits were required Professor CUMMINS, in reply, said that he found himself increasingly sympathetic to the view that there existed differences in racial susceptibility After some generations of intense endemicity no appreciable evidence of increased resistance was found in some races He laid great stress on the influence of habits and modes of life to which peoples were accustomed He preferred the term 'inherited resistance"—varying potentials of resistance—to "inherited susceptibility" The study of the disease in children would, in his judgement, prove the key to these problems

ANTITUBERCULOSIS SCHEMES

The subject of antituberculosis schemes was introduced by Dr A S M MACGREGOR He pointed out that the relation of such schemes to the public health presented two aspects the progress and efficiency of current preventive measures and the nature of the disease The preventive measures in tuberculosis had had much effect on public health generally—for example, in determining its present aspect towards housing standards and environmental hygiene Prompt diagnosis early treatment, and efficient after-care factors which controlled modern tuberculosis work were the fundamentals of public health principles He (the speaker) believed that the dispensary did its best social, medical and preventive services as an outpost of the public health department the main principles on which it should work should be that it had all possible modern facilities for diagnosis including efficient observation He thought that the new Local Government Act would work to the interest and competence of the dispensary physician, bringing him again more into line with the progress of general medicine The dispensary had no effect on the incidence of tubercle in young adults because, in his experience, the disease had been sporadic rapid and already far advanced when discovered The other great difficulty was the discovery of cases among contacts As far as institutions went he thought too much stress might have been laid on the pure sanatorium as an instrument in treatment of early cases What was required more to-day for the general population was hospitalization, 60 per cent of his cases resided in one and two-apartment houses, so that domiciliary treatment was impossible, and the sanatorium-hospital was a necessity His cases were hospital against sanatorium in the proportion of 4 to 1, half his cases were advanced when reported, and three quarters of the patients had died in two years He believed that the arguments in favour of colonies depended on considerations outside the [illegible] public health With regard to the nature of the disease he pointed out that the rate of influx of susceptibles and the number of slum areas in any city [illegible] the incidence of tuberculosis to vary Investigation [illegible] there was little decline in tubercle between [illegible] 15 and 25 the decline had been above and [illegible] this age group There had been a fall of 50 per cent in the age group 35 to 45 showing that there [illegible] much more infection in middle age, while [illegible] about cases of the young adult There [illegible] domiciliary tuberculosis in Scotland, but a [illegible] done in an attempt to diminish incidence of infection and to introduce [illegible] There had been marked reductions in death rates as contrasted with the first decade of the century He strongly advocated pasteurization, while he believed it had assisted materially in the decline of bovine tuberculosis in Scotland

Dr R E WODEHOUSE (Ottawa) described Canada's experience as regards tuberculosis programmes He said that the field work in Canada was in the direct charge of provincial departments of health The institutional care of tuberculosis was, for the most part, under the direction of other than Government departments, but nearly one-third of the estimated cost of maintenance was contributed by the provincial Governments The best diagnostic work, in so far as civilians were concerned, was carried on by what were known as travelling chest diagnosticians, these were medical men who were usually ex-sanatorium staff, and who visited, on an average once in three months, different centres in order to examine cases referred by the district practitioners Home visiting and school inspection nursing services were not uniform over Canada, where they existed they were maintained by voluntary committees in small centres, and by official authorities in larger ones Canada was marking time on the question of after-care or village settlements, and was waiting to copy the most useful and economic practice evolved elsewhere He believed that real results were being obtained by the efforts now put forth, and that the feature which had had the greatest influence up to the present was the provision of sanatorium beds The best results had been obtained under the management of voluntary committees, owing to the predominance of indigent cases cared for Where a sanatorium was administered by a voluntary committee the administration had to be economic, efficient, and humane, so that it might attract the tuberculous to seek treatment and the municipalities and public to contribute more towards construction and maintenance He concluded by enumerating the efforts of the Canadian Tuberculosis Association, which were mainly to stimulate the routine examination of presumably well school children, to obtain greater action in regard to the care of North American Indians, to hasten the provision of stronger efforts in the Maritime Provinces, where the death rates had been highest, to emphasize the importance of full-time medical services in industry, and to devise some approved form of after-care of discharged sanatorium cases Dr McDOUGALL of Preston Hall, at the request of the chairman, outlined the scheme of that institution, and after a short discussion Dr Macgregor summed up the proceedings

Friday, August 29th

OPERATIONS AND DEMONSTRATIONS

THE third session of this Section was held at the Winnipeg General Hospital, and was of a clinical and practical nature Operations were performed, and demonstrations by lantern and models were given by the President (Mr BISHOP HARMAN) and Mr A J BALLANTYNE Mr A W ORMOND (London) gave a detailed, illustrative account of Gonin's operation for detachment of the retina He did not regard the operation as likely to be a success in every case of detachment, but he thought that up to the present time it was the best contribution that had been made to the methods of dealing with that most difficult and unsatisfactory condition He had himself been able to record a few successes He would certainly aim at improving his technique with a view to getting the results claimed by Gonin Mr Ormond also demonstrated some excellent drawings of the eye conditions associated with Mongolian idiocy, leprosy, and other diseases Mr VERNON CARGILL showed some stereoscopic slides and a series of photographs, coloured and uncoloured, of fundus conditions, which he said were very useful for case records He mentioned that with a little practice the interpretation of the uncoloured photographs became a comparatively easy matter The members were much interested in his instruments brought from Amritsar, with which he demonstrated the operation of "couching" the lens as practised by the Indians

Definition of Blindness

Sir James Barrett (Melbourne, Australia) asked for a definition of blindness which would be applicable for industrial purposes, and for admission to institutions for the blind in the course of his duties he frequently had to give an opinion The standards he used in Victoria were total blindness = inability to count fingers at 2 metres, almost total blindness = vision less than 6/60, partial blindness = vision less than 6/36 He frequently found people endeavouring to secure entrance into blind institutions with far higher standards than these and he was anxious to have the support of the British Medical Association in fixing a standard Mr Bishop Harman replied that, although a standard similar to that of Sir James Barrett was what was used in Great Britain, it was difficult to fix a numerical standard to decide the question whether a person was blind for economic purposes since the limitation of the field of vision was an important consideration In Great Britain the opinion of the ophthalmic surgeon was generally accepted after a thorough review of the case He proposed that Sir James Barrett's problem should be referred to the Council of the Association

Defective Vision and the Pilot Service

Sir James Barrett commented on the necessity for a complete ocular examination in the case of a man in the pilot service who had had any accident with his ship As oculist to this service in Victoria he had in mind one very instructive case A pilot had missed a buoy and run his ship on to a sandbank, the explanation given at the inquiry was that at the moment of reaching the buoy a flight of birds obscured his vision This was accepted but not long afterwards the same man was involved in a collision, and his sight was then found to be defective Sir James Barrett considered it a most anomalous thing that after an accident these pilots should be medically examined in every other respect except in the matter of the condition of the eyes It was decided to refer this question also to the Council of the Association

Interesting cases were presented to the Section by Professor T Hepbert Bell and Dr F D McKenty of Winnipeg but owing to the lateness of the hour they had to be examined later, Mr Bishop Harman, Mr Cargill Dr Ivor Campbell, and Dr Whiteside Robertson then discussing them

---

SECTION OF BACTERIOLOGY PATHOLOGY PHYSIOLOGY AND BIOCHEMISTRY

Friday, August 29th

Histology of the Glioma Group

At the final session with Professor M J Stewart, a Vice-President, in the chair, Professor William Boyd (Manitoba) read a paper entitled "The glioma group studied by ordinary histological methods" Referring to Bailey and Cushing's classification, to Penfield's brilliant contributions, and to the methods of Cajal and his pupils of the Spanish school of neuro-pathology, which constituted the basis of all recent work, the speaker reported a series of 31 cases of which 16 were classified as astrocytomata 9 as spongioblastomata, 1 as astroblastoma 3 as medulloblastomata, and 1 as ependymoma, one was unclassified He emphasized the fact that a diagnosis could be made satisfactorily by ordinary histological methods and that subdivision was of importance because of the different clinical behaviour of these tumours Professor Wilder G Penfield (McGill University) stated that from the point of view of the neurological surgeon the present classification of gliomas was of great assistance

Glomic Tumour

Dr L C Simard (University of Montreal) contributed an account of glomic tumour of the forearm, illustrated by a series of beautiful slides prepared by Masson's technique The speaker recalled that in 1914 Masson described the occurrence of small (benign) tumours under the nail, and termed the condition anterior angioneuromyoma, or glomic tumour Clinically these tumours generally also under the nail, which bulged exhibiting a bluish growth There was piercing and almost unbearable pain. The growths might occasionally arise in the skin and forearm Dr Simard reported a case of the forearm type in a man aged 45 He added that Masson had associated these pathological structures with certain apparatus of glomerular like structure, normally present at such sites he believed them to be the regulators of the peripheral circulation Answering questions by Professors Stewart and Muir, Dr Simard stated that a total of about twelve or fourteen cases had been reported, of which only five were elsewhere than on the finger

Physiology and Pathology of the Endometrium

Professor J H Teacher (University of Glasgow) read a paper on the normal structure of the endometrium and decidua and the menstrual cycle He said that there was only one method by which the ages of human corpora lutea and decidua could be determined—namely, from the history of properly dated young human ova A corpus luteum only signified the ripening of an ovum its relation to menstruation was problematical The speaker preferred to ignore the classical description of the menstrual cycle and to accept the theory of Heape originally formulated thirty years ago, in its present form it stated that (1) the menstrual cycle in the human subject normally proceeded all the year round, but ovulation and corpus luteum formation occurred only from time to time (2) there was no regular date of ovulation and the lunar rhythm of the cycle was not due to ovulation nor to any as yet known cause, (3) in the absence of fertilization it was probable that several ovulations occurred in succession, as in polyoestrous mammals like the mare or guinea-pig Professor J B Collip (McGill University) emphasized the importance of considering as distinct entities the two types of hormonal activity, for proof of which he mentioned the work of Loeb, Doisy, Corner, Wiesner, and others He referred to non fertile oestrus at normal puberty as being the usual condition rather than a rarity in mammals he based this conclusion on the work of Evans and Long, Mirskaia and Crew, and his own personal observations He commented on the association of non-fertile cycles with the absence of corpora lutea in the rat, and the relationship of these observations to those on the occurrence of menstruation in absence of ovulation in monkeys (the Hartmans and Corner) In his opinion the whole subject of sex physiology was in the melting pot and before final conclusions could be formulated the work of the biochemist, physiologist and pathologist would have to be correlated and greatly extended

Intra-epithelial Growth of Carcinoma

Professor Robert Muir (University of Glasgow) read a paper dealing chiefly with the growth and extension of cancer cells in the epidermis Such an occurrence he said, could be met with under three conditions (1) The cancer cells might reach the normal epidermis by direct spread from an underlying growth, thereafter extending within the epidermis (2) The cancer cells might reach the epidermis by continuous growth from the duct of a gland opening on the surface the outstanding example of this was Paget's disease of the nipple occurring secondarily to intraduct carcinoma (3) The cancer might start in the epidermis itself and spread within it instead of infiltrating the subjacent tissue as was usually the case In some apparent instances of this type however, the point of origin might be in the skin appendages In all three conditions the growth of the cancer cells in the epidermis apparently met with considerable difficulty and was accordingly relatively slow It was not uncommon to find the cells scattered in the rete malpighii, and sometimes spreading widely into the sebaceous or sweat glands The speaker had never seen a clear example of a return from the epidermis to the connective tissue although its possibility could not be excluded It could at least be said that once the intra-epidermal extension of the growth had been established the cells tended to be restricted to the epidermis.

THE PLASMA PHOSPHATASE IN BONE DYSTROPHIES

PROFESSOR H D KAY (University of Toronto) contributed an account of the phosphatase of the blood plasma in bone dystrophies He had extended to bone pathology the rôle in bone formation which Robison first suggested in 1923 for the enzyme phosphatase A reasonably accurate method has been evolved for the determination of the amount of this enzyme present in 1 c.cm of plasma, and the method has been applied to the plasma of patients suffering from various types of disease The enzyme actively present in a localized zone in the growing bone hydrolized the phosphoric esters in the circulating blood, bringing about deposition of insoluble lime phosphate salts in the ossifying zone Whereas in patients with diseases in which the bone was not involved the amount of phosphatase was normal, or only above it, in patients suffering from bone diseases in which a large portion of the skeleton was involved the plasma content of this enzyme was greatly increased Such an increase had been found in osteitis deformans, in generalized osteitis fibrosa, in osteomalacia, in infantile, adolescent, and renal rickets, and also in one very severe case of calcinomatosis of the spine and pelvis It was not present in arthritis, osteomyelitis, and bone disease of a purely local nature, nor in fragilitas ossium The rise in phosphatase in generalized bone disease was not necessarily associated with any changes in the serum calcium or inorganic phosphate The amount of increase found was from ten to thirty times the normal average, far beyond the limit of error of the method and the normal extent of variation Professor Kay considered that whereas up to the present in bone diseases there had been known only two useful variables in the blood constituents, a third, the plasma phosphatase, might now be considered as being definitely available to assist in the attack on the problems of bone pathology DR D R MCCULLAGH (Cleveland Clinic), instancing the usefulness of the method, mentioned that a sample of blood from a case strongly suggestive of generalized osteitis fibrosa (a condition confirmed by subsequent removal of a parathyroid tumour) had been sent to Dr Kay without comment or information, the latter had reported that the plasma indicated extensive bone pathology

COAL MINER'S LUNG

PROFESSOR S LYLE CUMMINS (Cardiff) outlined the earlier work on anthracosis, including the evidence from experiments on animals by Haldane and others that coal dust and soot in the lungs were readily taken up by phagocytic cells and swiftly removed from the respiratory apparatus, and also the observations of Mavrogordato that if guinea-pigs were first exposed to silica dust and then to coal dust, the latter instead of being easily removed, was held up in the lungs, which then presented the typical appearance of anthracosis Professor Cummins wished to focus attention on the dust risks to which coal miners were exposed, and to modify the current view that this industry was one in which the danger of pneumoconiosis might be to a great extent ignored Tattersall (1926) had described silicosis in South Wales coal miners working in "hard headings" the speaker in 1927 had described the pathological and clinical findings in a "hard heading" worker, and had suggested that the accumulation of coal dust in the lungs was caused by an underlying silicosis which had led to interference with the lymphatic drainage of the lungs That such in effect might follow a low degree of silicosis, insufficient in itself to produce serious interference with health was suggested by the fact that in this case the lung ash contained only 12 per cent of silica There was urgent need of further pathological, histological, and chemical investigations For the past two years the speaker, in conjunction with Dr A T Sladden, had been devoting attention to this side of the question Up to the present 38 lungs had been examined, Dr Tideswell being responsible for the chemical analyses a limited number from persons engaged in industries other than coal mining serving as controls They showed no marked accumulation of coal dust, and the lung ash contained about 1 per cent of silica A second group showing definite anthracosis, although the patients had exhibited no lung disability, gave a lung ash silica content of 5 to 20 per cent, while in a third, from patients definitely exhibiting lung disease, the silica content ranged from 25 to 42 per cent, this group had nearly all worked in "hard headings," and the lung tissue showed an almost universal blackening Summarizing his results Professor Cummins concluded from his series that the greater the amount of silica the more marked was the fibrosis, and, in consequence, the more complete was the blockage of lymphatic channels and the more intense the accumulation of coal dust in the lungs. Anthracosis was silicosis complicated by coal dust accumulation Unlike simple silicosis it might lead on to serious respiratory disability and death without the intervention of tuberculosis Bronchitis, the characteristic terminal lung disease of old coal miners, appeared to bear the same relation to anthracosis as tuberculosis did to the silicosis of gold miners on the Rand

---

SECTION OF TUBERCULOSIS

Thursday, August 28th

TUBERCULOSIS IN CHILDREN

PROFESSOR S LYLE CUMMINS, President of the Section, occupied the chair at the second session, when the subject of tuberculosis in children was opened by Dr MAURICE MCPHEDRAN (Philadelphia) He began by stressing the different appearances in the lesions in childhood and adolescence The interaction of seed and soil presented a complex problem as regards the type, age, sex, and resistance, the significance and correlation of each could be shown by comparison of the x-ray representation of the types of tubercle in children and adults with the normal picture He insisted on the importance of using x rays, and pointed out how they might reveal the only evidence of activity He illustrated his contentions with quoted cases of tuberculosis associated with normal pulse, temperature, blood count, and sedimentation rate He showed how *diagnosis could be similarly aided in the common non-tuberculous basal lesions* DR RAY M PRICE (Toronto) dealt with the bacteriology of tuberculosis in children From the standpoint of incidence, she said, the human was the most important of the various forms of childhood tuberculosis, the bovine type came next, and its morbidity was to a degree parallel with the amount of tuberculosis in the bovine species, the avian type was an occasional factor Referring to research being carried on in Toronto, she mentioned 207 medical and surgical cases of tuberculosis in children under 14, these showed that of 65 cases of medical tuberculosis 63 were due to the human type of tubercle bacillus and 2 to the bovine type Pulmonary tuberculosis was essentially due to infection of the human type Of 75 cases of bone and joint tuberculosis there were 72 in which the infecting organism was human, while 3 were bovine In 30 cases of tuberculous cervical adenitis 17 were human and 13 bovine, while of 20 cases of renal tuberculosis 18 were human and 2 bovine Only 2 cases of primary abdominal tuberculosis were encountered, and both proved to be bovine One case of generalized glandular tuberculosis was found to be of the avian type The research workers had interested themselves in the study of raw market milk Of 250 samples from small dairy farms supplying Toronto with milk for pasteurization only 3·7 per cent proved to be infected, but in striking contrast 26 per cent of pooled bulk milk prior to pasteurization proved to be infected The work went to show that the effective pasteurization of milk eliminated the menace of bovine tuberculosis DR D NABARRO (London), who discussed mediastinal glands and primary lung tubercle in children, said that his observations of the last two years had proved that the primary lung focus arose from insufflation, and that it gave rise to secondary tracheo-bronchial glands The primary focus was usually found immediately beneath the pleura, and on the right as against the left side in the proportion of 3 to 2 His research led him to believe that if a lung focus was present tuberculous mediastinal glands would be discovered, if glands were found to be infected a lung focus would be present His work at Great Ormond Street had shown that in 424 post-mortem examinations on children

under the age of 12 15 8 per cent had shown tuberculous disease in only one case had he found lung signs with no corresponding change in the mediastinal glands

Dr W J Donnir (Weston, Ontario) emphasized the need for more adequate measures for the prevention of tuberculosis in childhood He believed that the infection rate was a point of paramount importance Since the sources of infection were well known, and the conditions of development recognized, the hope for the future lay in the active and persistent application of the knowledge already available While he welcomed research, it would be better to apply what was already known He stressed the application of the following measures (1) adequate means of protection, (2) the removal of all children under the age of 16 from active open cases (3) the adequate prevention of expectoration in public places (4) proper medical inspection of children, with immediate segregation on the discovery of a lesion, (5) the removal from schools of all open cases among pupils or staff, and (6) appropriate treatment being carried on for some years It might, he added, be claimed that such a scheme would produce a generation without resistance from lack of immunity, but he believed that such fears were groundless Dr PARSONS commented on the importance of pasteurization in the fight against tuberculosis in children He pointed out that the obtaining of pure herds, free from tuberculosis, would be the ideal, but would take generations to accomplish The best form of control was pasteurization The evidence of its efficiency was the presence of tubercle bacilli in raw milk and their absence after pasteurization The practical result of its application on the incidence of tuberculosis and its mortality could be determined from a study of non pulmonary disease in the age groups of 1 to 4, or even of 1 to 14 Bovine infection had a preference for the lymph nodes in early life It was evident from their work in Toronto that the pasteurization of milk was showing tangible results They now saw very little glandular tuberculosis, while peritoneal tuberculosis was a rarity From 1911 to 1915 hospital records indicated 0 025 per cent non pulmonary tuberculosis, the figure for 1924 to 1928 inclusive was 0 013, a reduction of 50 per cent He concluded by pointing out that pasteurization did not harm the milk Dr J A JAMES (Montreal) dealt with childhood tuberculosis and housing He submitted figures connected with a survey of 1,256 cases of tuberculosis at the Bruchesi Institute Complete investigation of the cleanliness and peopling of the houses was made, and his conclusions were that in Montreal the problem of the slum did not exist while the dwelling by itself was clean He had found that the situation was aggravated by the overcrowding of homes and the overpeopling and lack of aeration in the central wards of the city He had concluded that family contamination and underweight in children were the dominating problems, and he believed that the solution for the future was dependent on the education of the people and the protection of childhood He stressed the importance of giving all possible help to students and physicians who wished to investigate tuberculosis In the end, the problem lay in early diagnosis, and this fact presupposed in every physician the required competence to discover the disease on its first symptoms Dr BRUCE CHOWN (Winnipeg) discussed tuberculosis in childhood with special reference to the pulmonary form No one could be dogmatic about the etiology of tuberculosis in childhood, since what applied to one community did not necessarily apply to all others In Winnipeg he had come to look on the problem as one almost entirely of human infection, since the bovine tubercle bacillus as a causative agent was so rare as to be a curiosity while the human bacillus was so often encountered as to be appalling It was a common mistake to believe that tuberculosis early affected the child's nutrition Cough was more often present than mentioned and pleurisy with effusion was often the first definite symptom In diagnosis he stressed the value of getting a history of contact a positive tuberculin reaction and an x ray film The tuberculin test ought always to be correlated with the type of community in which it was practised he believed that a positive test was not only of diagnostic value for one particular child, but pointed the way back along which the bacillus had come He would warn against the all too-frequent and unjustified diagnosis of hilar increase and enlarged hilar glands In treatment he was constantly surprised to find how well an infant could handle a quite extensive infection if kept isolated from adult re-infection No child with a positive tuberculin reaction should be declared free from pulmonary tuberculosis without a good x ray film properly interpreted A very full and interesting discussion followed

SECTION OF LARYNGOLOGY AND OTOLOGY

Friday, August 29th

NASAL SINUS SUPPURATION PERSISTING AFTER OPERATION

Dr PERRY GOLDSMITH (Toronto) opened the second day's discussion, with Dr S W PROWSE, Vice-President, in the chair He said that he was not alone in his view that there had been a great deal of unnecessary and unwise surgical zeal devoted to the nasal accessory sinuses Persistence of discharge from any nasal accessory sinus following operation did not necessarily demand further surgical measures of a more radical nature The main symptoms which troubled the patient, such as pain or discomfort in the head, nasal or post-nasal discharge, nasal obstruction, recurring head colds, and mental depression, might have been so greatly benefited that even if some nasal or sinus secretion persisted it was not usually of sufficient importance to require further surgical intervention The type of patient was of importance in determining the treatment the neurotic patient might simply require to be encouraged not to worry about a little nasal discharge Dr Perry Goldsmith reviewed some of the reasons for failure in the operative treatment of the different nasal sinuses He felt that the use of ionization with zinc in large irregular sinuses was likely to be a useful and hopeful adjunct, though he had had little clinical experience of it A not uncommon cause of persistent discharge from an antrum that had been operated on by this method was failure to recognize frontal and ethmoidal disease He preferred the canine fossa route in operating on the maxillary antrum, because it gave much better access than the intranasal route In all cases it was better to remove the anterior third of the inferior turbinal Assuming an antrum to have been thoroughly cleared of all progenic oedematous mucosa and an efficient opening made into the nose, it might be some months before all noticeable secretion ceased The patient might have poor recuperative powers owing to ill health produced by anaemia, tuberculosis syphilis, chronic nephritis or any debilitating disease His manner of living habits diet and even the atmosphere in which he worked, might have a bearing The heavy, rapid, immoderate eater and drinker, with chronic intestinal sepsis and constipation did not clear up well after sinus operations Lack of exercise and confinement indoors had a definite influence Many patients with oedematous manifestations of their sinus mucosa had as an underlying factor an allergic state The persistence of suppuration following operations of the ethmoid was in most cases due to free and spontaneous drainage not having been provided Mr A J WRIGHT (Bristol) said that one factor of the utmost importance in the treatment of nasal sinus suppuration was that of time many so-called incurable cases cleared up eventually Dr A LOGAN TURNER (Edinburgh) with the aid of a series of excellent lantern slides insisted on the importance of the part played by the ethmoidal cell labyrinth in maintaining the nasal discharge This was a factor which must not be overlooked in the consideration of the subject by some it was regarded as the key position He showed slides illustrating the development of the various groups of border cells' the more extensively these were developed the more difficult became the problem of successful drainage of the ethmoid cells There were many cases in which no intranasal operation however radical could reach every infected ethmoidal cell and the question of the advisability of an external operation might be usefully discussed.

DR M F ARBUCKLE (St Louis, U S A) said that allergy was a condition that had been mentioned with regard to post-operative nasal sinus suppuration he thought it deserved more attention from the rhinologist Many persons afflicted with headache, asthma, chronic bronchitis, hay fever, nasal obstruction, abnormal nasal discharge, and the like consulted the rhinologist or the internist, and in many cases they had had one or more nasal operations without relief A very considerable percentage of such cases represented persons who were suffering from a so-called allergic reaction, and the most important step in their treatment was the discovery and removal of the offending substance or substances, which often brought about most unexpected and striking results Professor G W FIFTCHER (Winnipeg) said that, although the border-line between chronic non-suppurative and chronic suppurative sinus disease was not strictly marked, and one often merged into the other the main picture stood out clearly Chronic non-suppurative inflammation was much commoner than was generally supposed and was often described by the patient as a "chronic nasal catarrh" There was no purulent discharge present, except in periods of acute infection MR TILLEY had claimed that these cases were often overlooked by the physician, since transillumination revealed no opacity A radiograph however, showed an opacity caused by degenerate or thickened membrane The symptoms in these cases were not marked They consisted of excessive mucoid discharge from the affected cavity and mild attacks of neuralgia in the first and second divisions of the fifth nerve Diagnosis was made by x-ray examination and puncture, which might yield a mass of thick, glairy mucus Pathologically this was essentially a low-grade inflammation resulting in oedema and thickening of the mucous membrane The cellular elements were very scanty The cilia might be present at certain parts and scanty in others, and polypoid changes might be present Hyperplasia of the glands occurred and the formation of cystic dilatations in the sinus Chronic suppuration of the maxillary sinus was characterized by purulent nasal and post-nasal discharge from the affected cavity or cavities Other symptoms that might be present consisted of supra-orbital pain headache at time tendency to contract colds, nasal obstruction, cough and chronic chest sequelae This was the ordinary form of mucoid disease, being much more common than the form previously described The process was also much more active and the symptoms more pronounced The pathology differed from the catarrhal form inasmuch as infiltration with cells was much more marked The membrane was, as a rule much thickened This might be uniform or patchy in distribution Patches of granulation occurred sometimes and areas of completely desquamated epithelium Polypi might be found springing from any part of the walls Caries and necrosis of the bone did not occur except in cases of syphilis and tuberculosis In long-standing cases fibrosis developed, especially in the deeper layers The excellent work done by Knowlton and McGregor was worthy of note The antral linings in dogs were removed completely in three cases it was found that regeneration of the mucous membrane commenced in the period of one to two weeks, at the end of three months it was largely completed, and at the end of six months it was practically impossible to tell the difference from normal antral lining the cilia had been so completely restored

MR I I MUECKE (London) said that the more he operated on the nose the more conservative he became He thought that the turbinates should not be removed, he looked on them as among the most important tissues in the body Simply on stopping irrigation a nasal discharge frequently cleared up He had abandoned the intranasal method of operating on the antrum, since one could not see round the corner, and he preferred to leave the sphenoidal sinus untouched He believed strongly in correcting any gross septal deviation to aid nasal drainage DR MCGREGOR (Toronto) described experimental work on the nasal sinuses He had also been interested in the eosinophils for some time with respect to asthmatic conditions Such patients varied surprisingly from time to time and the eosinophils disappeared almost completely in the presence of almost any infection SIR STCLAIR THOMSON (President) said that the slides shown by DR LOGAN TURNER indicated why nasal suppuration was sometimes inevitable in spite of any operation They showed, too, that one should be tender of the reputation of one's colleagues who had operated on such cases In opposition to MR MUECKE, he considered the sphenoidal sinus the most satisfactory one for operative treatment The ethmoidal labyrinth might be termed the *bête noire* of the rhinologist Vaccines, in his hands, had proved absolutely useless

A SAFE METHOD OF DEALING WITH ETHMOIDITIS

MR I A PETERS (London) read a paper in which he urged that in all cases of ethmoiditis radiograms should be taken to obtain information as to the infection of the sinuses Radiographic pictures of the frontal sinus were usually definite, of the maxillary sinuses less definite, and of the sphenoidal sinus very indefinite He considered that primary ethmoiditis operations should, except for simple polypus, consist in removal of the middle turbinal and intranasal drainage of the sphenoidal sinus and maxillary antra Excision of the middle turbinal should be carried out by Luc's forceps, either in its entirety by gripping the body of the bone or by nibbling from the anterior end and removing the opened cell Ethmoidal cells should be opened later under local anaesthesia only if symptoms of closed empyemata appeared extensive opening of these cells was rarely indicated

DEAFNESS IN SCHOOL CHILDREN

DR HORACE NEWHART (Minneapolis) read a paper, illustrated by lantern slides, on recent efforts to prevent deafness among school children He gave details of the work he had been carrying out in Minneapolis, showing the successful results brought about by the thorough organization of the diagnosis of deafness and its preventive treatment in the schools of that city DR AUSTIN A HAYDEN (Chicago) looked upon DR NEWHART as a revolutionary in otology He insisted on the value of the 2 A audiometer, which in his opinion standardized the testing of the hearing DR HAYDEN also showed an interesting cinematograph film dealing with the work of the League of the Hard of Hearing

TREATMENT OF OTOSCLEROSIS

MR SCOTT STEVENSON (London) read a paper on otosclerosis, with special reference to treatment He said that it appeared to be almost anathema among otologists to mention treatment with respect to otosclerosis yet the subject continued to interest and perplex them on both sides of the Atlantic He went on to review recent methods of treating otosclerosis which had been reported including the administration of parathyroid extract by E Watson-Williams and the operative treatment suggested by M Sourdille so far he had found nothing to displace the electrophonoride method of Zund-Burguet, which he had employed with a certain degree of success for some years, in spite of the criticisms the method had received at the hands of many otologists

---

UNDER the auspices of the National Association for the Prevention of Infant Mortality and for the Welfare of Infancy a course of post graduate lectures on maternity and child welfare will be given from October 13th to December 15th on Mondays from 6.30 to 7.30 p.m. in the lecture hall Carnegie House, 117 Piccadilly, W.1. This course is intended to prepare candidates for the post graduate certificate of the association Tickets, which cost 7s 6d are obtainable from the secretary at the above address Another course, consisting of elementary lectures on infant care in preparation for the crèche nurses elementary certificate, will be held at Carnegie House, from October 9th to December 11th, on Thursdays, from 7.30 to 8.30 p.m. Matrons of crèches, not fewer than two of whose probationers or other workers are attending the course, are invited to accompany their students free of charge The cost of tickets for the whole course of ten lectures is 10s., and must be applied for in advance to the secretary, National Society of Day Nurseries, 117, Piccadilly, W.1.

British Medical Journal.

SATURDAY SEPTEMBER 27TH, 1930

THE FILTERABLE VIRUSES AND PRACTICAL MEDICINE

THE gradual lifting of the curtain on the filterable viruses is one of the most fascinating movements of our time, and accordingly the discussion on these specific pathogenic agents in relation to practical medicine which was introduced by Lord Dawson of Penn in the Section of Medicine at the Winnipeg Annual Meeting last month, is in good season. Moreover, as the present year has witnessed the demonstration by a group of clinical and laboratory workers at the London Hospital that psittacosis is due to a virus of this nature, and this observation has since been abundantly confirmed by others, the choice of Dr. S. P. Bedson to open the discussion was singularly appropriate. His paper, which is printed this week at page 505, comprises a review of the present state of knowledge of these disease agents and its application to clinical medicine. It is an admirable survey of the progress that has been achieved, while at the same time no secret is made of the difficulties—some of them formidable—that remain to be surmounted. The problem of the nature of these viruses is indeed most perplexing and of far more than academic importance. During the past thirty years the list of diseases, both of plants and of animals, which are due to agents of this class, has grown so large as to make it imperative to understand the nature of the agents and so be in a position to deal with their ravages in a scientific and more successful manner.

The view taken by Dr. Bedson that the filterable viruses are nothing more nor less than minute living micro-organisms akin to bacteria is one that is shared by a considerable number of those who have studied them closely in the light of an extensive experience of the more easily handled pathogenic bacteria. With each step forward in our knowledge of these viruses the line of demarcation between them and the bacteria becomes less and less obvious, and I look forward with some degree of confidence to the time when the filterable viruses and bacteria will be merged into one large group, inside which of course there will be slight differences—subgrouping—just as there is in the case of bacteria at the present time. It is difficult to see how, on the evidence to which he refers, any other view is feasible. Moreover, much of the progress that has been made during recent years in the elucidation of these viruses is directly due to the application of knowledge previously gained in the practical study of bacteria, and it is possible, and even probable, that additional advances will be made before long by further application of the same principle. Was it not William Harvey who wrote: "There is but one road to science—that to wit in which we proceed from matters more known to matters less known, from matters more manifest to matters more obscure"? Speaking generally, the trend of recent developments in the study of filterable viruses is to bring these infections more and more into line with those produced by the ordinary pathogenic bacteria.

The chief interest of practical medicine in these viruses lies however in the applications that can be made of new knowledge gained in the experimental laboratory to the prevention, diagnosis, and treatment of the specific diseases produced by them. Dr. Bedson's paper contains an account of what has been accomplished in these several directions. The employment of living virus for purposes of prophylaxis, even when the virulence is reduced by suitable measures, is obviously an early stage in the practical prophylaxis to the filterable viruses, and in view of recent experience with vaccinia improvement in this direction is especially desirable. Exploitation for purposes of diagnosis of the specific antibodies that are certainly formed against some of the filterable viruses, and probably against all, has hardly begun, but the successes already accomplished and described by Dr. Bedson in the course of his survey indicate that further advances may be expected in this direction before long. Finally, it would seem that the method of passive immunity has already been applied to the prophylaxis of poliomyelitis and measles with encouraging results. There is ground therefore for hoping that further study of the serum of hyperimmunized animals in the experimental laboratory may lead in due course to the introduction of a successful form of treatment for virus diseases by specific serum, the lack of which is at present only too obvious.

THE TRAFFIC IN DANGEROUS DRUGS

THE Assembly of the League of Nations at its meeting last year somewhat tardily arrived at the conclusion that the magnitude of the illicit traffic in dangerous drugs, disclosed by the reports of its Advisory Committee, could only be dealt with effectively by the strict limitation of the production of such drugs to the amounts required for medical and scientific purposes. The resolution passed unanimously by the Assembly on September 21st 1929 stated that, impressed with the disclosures as to the large quantities of dangerous drugs still passing into illicit traffic, and desiring that if possible steps supplementing the Convention should be taken without delay to limit the manufacture of dangerous drugs to the amounts required for medical and scientific purposes, the Assembly requests the Advisory Committee to prepare plans for such limitation, regard being had to world requirements for medical and scientific purposes. The Committee's report will be submitted to the Council, which will decide on the convening of a conference of the Governments in whose countries the above-mentioned drugs are manufactured and the principal consuming countries in a number not exceeding that of the manufacturing countries. It was thought that it would be necessary to hold a preliminary conference of the drug manufacturing countries before the summoning of the larger conference which would include representatives of both consuming and manufacturing countries, but on July 9th of this year the British Government informed the Secretary General of the League that the requisite material for the earlier conference was not yet available and that this conference contemplated for the end of July could not be convened. At a meeting of the Council of the League on September 18th it was announced that the larger conference on limitation of manufacture would be held on May 27th 1931, and that the preliminary conference of manufacturing countries would assemble in London on October 27th of this year.

It is clear that any scheme for the limitation of production must have regard to some standard for the legitimate requirements of the world for medical purposes. It will be remembered that some years ago a mixed commission of the Health and Opium Committees of the League reported that the medical use

should be considered the only legitimate use of the drugs, and that the use of opium as a stimulant, as in some tropical countries, was not regarded as legitimate It was later reported by the Health Committee that 450 mg of raw opium might be regarded as the medical requirement per head per annum As the result of a more recent investigation by the Health Section of the League on "world consumption of opiates and cocaine," a figure of 140 mg of raw opium per head per annum was arrived at, which covers the medical requirements of medicinal opium, morphine, heroin, and codeine, or less than one third of the earlier figure which had been propounded Taking the estimated population of the world at 1,950 millions, this would give the world requirement of raw opium for medical purposes as 273 tons Dr Wasserberg, commenting on these statistical results, regards this as an overestimate, and considers that "250 tons of raw opium and 6 tons of cocaine are sufficient for the world's requirements" It is true that the data from which these statistics have been compiled were incomplete, and the figures in many cases were merely estimates, but they appear to represent the best available basis on which to formulate—it may be provisionally—the world requirements When these results were considered by the Advisory Committee the representative of India intimated that "he had always been against the fixation of a standard," and "he thought it preferable to abandon any attempt to fix a figure for the world consumption" M Bremer, who for nine years was the able assessor to the Committee, drew attention to the wide diversities in the consumption of medicinal opium and morphine respectively in the United States, Great Britain, Switzerland, and Germany

Unless and until some more reliable standard of world requirements is forthcoming it will be well, in view of the appalling extent of the illicit traffic in the drugs in question, of which there are almost daily disclosures, to agree on some maxima of production in the manufacturing countries No one would wish that the supply for legitimate usage should anywhere be insufficient But it is now eighteen years since the Powers chiefly concerned undertook by The Hague Convention to co operate among themselves to prevent the use of these drugs for other than medical and legitimate purposes, and five years since this obligation was reiterated and endorsed by a yet larger number of Powers in the Geneva Convention

THE ETIOLOGY OF SUMMER DIARRHOEA

Although an alarming increase in gastro-enteritis cases among infants is no longer a common event of the summer months these maladies are still a persistent cause of infant mortality and morbidity, and investigations made to discover their origin have much practical importance Theories put forward at one time or another, which attribute the so-called acute intestinal intoxication to dietetic faults, to this or that organism or to parenteral infections (of which, according to W McKim Marriott, otitis media plays the principal part), have not met with general acceptance Now we have the record of a valuable investigation recently carried out at *Toronto* by M M *Johnston*, Alan Brown and F F Tisdall,[1] who made a precise study of 171 cases of intestinal intoxication during the period October 1928 to October, 1929 Some of the cases in this series occurred in the winter months, but with the onset of the warmer weather their numbers increased, reaching a peak some time after the hottest season of the year Most of the patients belonged to the "out-patient" class, a sufficiently well-defined social group, and of these 97 were males and 74 were females Only 5 were breast-fed; 5 had an unknown dietary history, 20 were receiving a mixed diet, and 141 were bottle-fed On their admission to hospital all these infants were examined for signs of ear involvement, and these were found in 45 Of the 126 whose ears seemed normal, 65 developed otitis media later, making a total of 109, or 63·7 per cent of the whole series Attempts were made to cultivate the organisms present in the ear, nasopharynx, and throat, but while streptococci were isolated in a large proportion of cases, particularly from the nasopharynx and throat, these organisms did not appear in pure culture Their failure to isolate one species of bacteria from the series, or a uniform flora, tells, in the authors' opinion, against the theory that masked mastoiditis is at the root of the intestinal intoxication They carried their investigation a stage further by studying a control series of 84 infants of the same age and social group, of whom 53, or 61 per cent, had otitis media on admission to hospital or developed it during their stay There was no significant difference between cultures of the organism from these patients and those from the intestinal intoxication group These findings, together with the fact that 126 out of the total of 171 infants had no otitis media after the intestinal symptoms had become established, seemed to the authors adequate grounds for discarding the theory that ear disease is an etiological factor in intestinal intoxication They then turn to the results of bacteriological examinations of the stools, and these are suggestive, for from no fewer than 129 of the cases they isolated a large variety of strains of Gram-negative bacilli In the control group, on the other hand, the organism isolated could be considered important in only two of the cases Agglutination tests were carried out with all available serums, and the demonstration of the presence of immune bodies in some of the serums seems to have established a connexion between the organisms found and the condition of the patients The final conclusion reached in this study is that intestinal intoxication in infants is an external infection caused not by one specific bacterial species, but by a variety of bacilli belonging to the colon-typhoid-dysentery group

INTERNATIONAL CO OPERATION IN HEALTH

THE British delegation (writes our Geneva correspondent), although it lacks this year the presence of the Prime Minister, is a very capable and effective one, and British contributions to the debates in the Assembly and its committees are full of initiative Nothing could have been better than the presentation of the account of the health activities of the League by Miss Susan Lawrence, Parliamentary Secretary to the Ministry of Health Miss Lawrence recalled with pride the fact that more than one international conference on the health work of the League had been held at the offices of the Ministry of Health in London To quote her words "In considering the work which is being done to improve conditions of health in my own country and the contributions we are making to health work in the British Empire by our School of Hygiene and Tropical Medicine, and by our most recent School of Post-Graduate Medical Education, the reflection presents itself to my mind how essentially similar, in spite of wide differences of local circumstances, are the problems which confront us all" The same difficulties, she added, repeated themselves in every crowded urban area, and in every scattered rural population, the experience of each country was immensely valuable to all the others The Health Organization had achieved results which proved how successful international co operation in health matters might become "International co-operation in health is relatively easy, there are few, if any, vested interests comparable to those which are

a bar to progress in the economic field, while in that even more difficult field of internat onal co-operation, the political, success is to be gained only by greater determination and more strenuous efforts to overcome more serious obstacles." The ten years' work of the Health Organization Miss Lawrence said, had been marked roughly by three stages first, the study and collection of information, secondly, the formation of general judgements on the basis of the material collected, and, thirdly, the stage of action As an example of the kind of inquiry which it was open to any country to ask the Health Committee to take up, she instanced the supply and distribution of radium Recently Great Britain found itself among the countries in which the public, as well as the Government, desired to extend the beneficial effect of radium in the treatment of cancer, and a large sum of money was acquired for the purchase of radium for hospitals But the question arose at once as to the best and most economical means of its application When this matter was placed before the Health Committee it was found that many other countries desired the same international study which had now been started, and already had produced most useful results Miss Lawrence paid a tribute to the medical director of the Health Organization, Dr Rajchman, and his staff, and to the Health Committee of the League, a small body, several of whose members had served from the foundation of the organization, and had spared themselves no trouble to give to the League the technical guidance which it needed "And we must never forget that it is the co-operation of the different health administrations, and the many experts who have given their services in different lands, that make it possible for us to record satisfactory progress from year to year" She considered that the inquiries with regard to infant mortality, which had been made in selected districts in seven countries, might well be extended Attention might be drawn to the high rate of mortality during the first days of life, together with the stillbirth rate, which apparently remained constant in most countries These conditions were largely due to obstetric causes, and an inquiry into maternal mortality might not only indicate means of reducing the death rate among women, but also of lowering neo-natal mortality Speaking of the courses of study, the so-called interchanges, which have taken place in three countries during the past year, Miss Lawrence referred to the new type of health work in Yugoslavia—one of the countries in question—designed to improve social and economic, as well as health, conditions This departure in the Balkans had been investigated by a group of fourteen health officers, who also spent a fortnight in Rumania, studying new features of the health and medical work there She also mentioned that several schools of hygiene, which had been established in different countries for the training of public health officers, had been exchanging experience and comparing methods, and the Health Organization had fostered this exchange by bringing the directors together for consultation and discussion, meetings for this purpose had been held during the last year in Dresden and Paris The discussion on the health work of the League, following Miss Lawrence's able summary, was continued by Sir Deva Prasad Sarvadhicary, former vice-chancellor of Calcutta University, who mentioned the work on plague in India, and also the need for obtaining a polyvalent serum for snake-bite by Viscount Inoue, member of the Japanese House of Peers, who testified to the interest of Japan in the development of public health in China, by M Zumeta, delegate of Venezuela, who suggested that the League should collect a body of information regarding medicinal plants, many of which, he said, were of specific value in certain diseases, but were quite unknown outside the regions in which they grew, and by Mr P E Coleman, a member of the Commonwealth Parliament, who said that in his view the League of Nations had achieved its greatest success in the field of health He also stated that the studies of the Cancer Commission of the League had been of special value to the Australian Government which had purchased large quantities of radium Australia was also particularly interested in the inquiry made by the League into the health position of certain Pacific islands Altogether, no one had anything but bouquets for the work of the Health Organization, and the Financial Committee passed without criticism the health budget for 1931, which involves an expenditure greater by £7,000 than the estimates for 1930, and by £15,000 than the actual expenditure for 1929 The Health Committee is appointed for terms of three years, and the new committee, the third in the history of the League, is holding its first session at Geneva at the end of September

THE HISTORY OF RUBELLA

In the July issue of the *Archiv für Kinderheilkunde* Dr Max Dirrigl of the children's clinic at Würzburg gives an instructive account of the history of the disease known in this country by the name of German measles, rubella, or its German name of röteln It may be said in passing that, though the "h" in röteln, as in most other words formerly containing "th," has been omitted for the last thirty years in Germany, this fact has not been generally recognized by British or American writers The term rubella, introduced by Veale in 1866, does not appear to be used except in English medical literature, but in Germany, as in other countries, rubeola is the usual synonym According to Dr Dirrigl this term first appears in literature in a Latin translation published at Vienna in 1492 of a work by Ali Ebn Abbas a Persian physician of the tenth century, entitled *The Knowledge and Cure of Diseases* Subsequent writers seem to have attached widely different meanings to the word Baillou (1574), for example, applied it to scarlet fever, Platen (1643) to small-pox, and Sauvages (1649) to measles Ludwig (in 1758), who seems to have been the first to differentiate röteln from measles, spoke of it as a milder disease, and the same view was expressed by Fritsch in a note in his translation of Cullen's nosology, in 1786 The earliest epidemic occurrence of rubella was noted by Jahn of Rudolstadt in 1807, but it was not until 1834 that the first detailed description of the disease was given by Wagner in Hufeland's Journal, followed by Thomas in 1872 in his article in Ziemssen's handbook In France the autonomy of rubella was maintained by Trousseau (1866), and in Russia by Nymann (1877) and Enko (1880) of St Petersburg This view, however, did not receive general acceptance until the International Medical Congress held in London in 1881, when, as the result of the communications of Cheadle, Eustace Smith, Squire Shuttleworth, and Charles West, the existence of rubella as a disease *sui generis* was finally established, in spite of the opposition of such notable authorities as Hebra and Kaposi, who maintained similarly that variola and varicella were manifestations of one single disease

TWINS

THE study of twins is interesting from many points of view To the eugenist it suggests the possibility of evaluating the relative importance of "nature and 'nurture," because, if one could measure the qualities—physical, physiological, and psychological—of monozygotic twins brought up under different environments, one would have as close an approximation as possible to a measure of pure environmental influence To the physiologist or paediatrist it is of interest to compare the anthropometric and physiological characters of twins with those of their brothers and sisters, since in this way some light might be thrown upon the respective shares of pre- and post-natal environmental factors in development The current

number of the *Eugenics Review* contains the first part of a memoir by Dr Percy Stocks describing the results of a research into the characters of twins based on measurements made in the elementary and central schools of the London County Council Dr Stocks has dealt *inter alia* with height weight head measurements blood pressure pulse rate respiratory rate and eye colour He has determined averages measures of variation and of correlation while taking care to allow for age in determining the weight of differences It appears that monozygotic twins tend to be taller and heavier than dizygotic twins while their brothers and sisters occupy an intermediate position as regards height but are superior to both in weight Monozygotic twins and to a less extent dizygotic twins tend to have higher blood pressure and quicker pulse and respiration rates than their brothers and sisters of the same ages The degree of resemblance between brother and sister born at different times is the same as in pairs of like sex born at different times and the degree of resemblance between dizygotic twins is not appreciably different from that met with in all pairs of children born to the same parents at different times Although at birth the mean difference in respect of various characters between members of a monozygotic pair has been shown to be of the same order as that separating members of a dizygotic pair, before school age is reached the former difference is approximately half the latter in respect of static characters and weight This differentiation occurs later in respect of blood pressure Various attempts have been made to evaluate the respective shares of "nature" and "nurture," and Dr Stocks points out the objections to which these are open tentatively he is inclined to rank height weight head dimensions blood pressure pulse and respiration rates in descending order of relative power of constitutional to environmental influences A very interesting section of the memoir is devoted to the problem of obtaining a practically applicable diagnostic criterion of monozygotism since information as to the existence of a separate chorion will rarely be available when one has to deal with adults while mere mental likeness may be misleading It is, as Dr Stocks points out extremely easy to reason in a circle If for example we assume that such or such a proportion of like-sexed twins are monozygotic in order that a particular diagnostic criterion may give this proportion of monozygotic twins in an examined sample only justifies the diagnostic method if the assumption is certainly correct Hence Dr Stocks has applied a number of tests which, even if some of them depend on assumptions are at least partly independent, and although he modestly fears that he himself may not altogether escape the charge of circular reasoning his methods seem to us cautious and satisfactory He concludes that the most satisfactory method is one which requires four head measurements and the child's finger-prints but that a reasonably good result can be obtained from finger-prints alone Clear practical instructions for the carrying out of the tests are provided It is perhaps superfluous to say that this memoir reaches the usual high standard of the Galton Laboratory in presentation and in

RICHARD VON VOLKMANN

In a sympathetic memoir[1] Professor Willy Anschütz of Kiel describes the life and work of Richard von Volkmann the pioneer of antiseptic surgery in Germany on the occasion of the celebration of the centenary of his birth on August 17th The son of Professor Alfred Wilhelm Volkmann a distinguished anatomist and physiologist at Halle Richard showed no special gifts in his early years, and it was not until 1855 shortly after his qualification, when he had to act as deputy for his sick chief, Professor Blasius director of the surgical clinic at Halle that his abilities as a surgeon became known forth Ten years later he succeeded Blasius in the chair of surgery at Halle and in addition to making valuable contributions to surgery and pathology founded the well-known collection of clinical addresses to which his name is attached Returning to Halle after the Franco-Prussian war the prevalence of wound infection raised the question of the reconstruction of the clinic As a last resource Lister Volkmann with some misgiving introduced Lister's antiseptic method with such marvellous results that for many years his clinic at Halle became the Mecca for surgical pilgrims In addition to bone and joint surgery, which had always been his favourite subject Volkmann contributed much to the advancement of orthopædics since he possessed a gift for technique and the solution of mechanical problems Mention should also be made of his work on cancer particularly in relation to its occurrence among workers in tar and paraffin Besides being a bold and successful operator Volkmann was an excellent teacher and counted among his pupils such well-known surgeons as Schede Kraske Sprengel Ledor Krause Heinrich Braun, and Hedenus Volkmann died at the comparatively early age of 59 at the height of his fame His native town of Halle of which he had been made a freeman erected a statue of him in front of the clinic where he had worked with such distinction

THE BRITISH ASSOCIATION'S APPEAL

In our notes on the recent annual meeting in Bristol of the British Association for the Advancement of Science we mentioned on September 13th (p 440) that it was intended to appeal for £50,000 as a centenary endowment fund Research has always been one of the primary interests of the British Association and several important investigations have been endowed by it There are normally in existence about seventy committees concerned with such researches or with inquiries into the state of various branches of science Grants have been provided for materials and instruments as well as for publication of the results Payments are not made to research workers the Association being essentially an organization for the encouragement of voluntary work in the cause of science Apart from the publication of its annual report and other necessary printings, which form a large item in the general accounts there has hitherto been no systematic provision for issuing a full record of the transactions at the annual meeting In undertaking the custody of Down House the British Association accepted liability for about £3,000 towards the restoration of the property and there are further commitments for upkeep The cost of celebrating the centenary next year in a fitting manner is another item of unavoidable expense It is hoped that a generous response to the appeal will enable the Association to extend its support of research to ensure the means of carrying out its imperial responsibilities, and to increase the facilities offered to junior students of science besides meeting those obligations which have already been mentioned Contributions should be sent to the General Treasurer British Association Burlington House W 1

The Harveian Oration will be delivered before the Royal College of Physicians of London on Saturday October 18th (St Luke's Day) at 4 o'clock by Professor John Beresford Leathes M B F R S

The Shorstein Memorial Lecture will be given by Mr H S Souttar F R C S at the London Hospital Medical College on Friday, October 17th at 4 15 p m His subject is radium in the service of surgery Members of the medical profession are invited to attend

THE DIETETIC TREATMENT OF LUPUS VULGARIS

A very interesting clinical experiment is now being conducted by Professor Jesionek at Giessen where he is in charge of the dermatological clinic of the local university. Professor Jesionek is also the head of a hospital of over 160 beds all of which are devoted to lupus vulgaris with the exception of a very few filled with patients suffering from allied conditions. This hospital is the only one in Germany exclusively devoted to this disease and the only other hospital in Europe of which we are aware which admits sufferers from lupus alone is the Finsen Institute at Copenhagen.

The hospital at Giessen was first erected in 1913, and had originally twenty-eight beds only, but since the war it has grown very considerably. Professor Jesionek has been in charge of it since the first, and its present size and importance is largely due to his efforts, and to his success in persuading the local authorities to finance the building and find the necessary funds for the upkeep of the institution. Professor Jesionek is well known to our profession as a prominent worker in actinotherapy, and of course light both natural and artificial, has played a conspicuous part in the treatment of the patients. He greatly prefers natural to artificial sunlight when he can get it, and the hospital, which is situated at the top of a hill, and looks south-east over open country, is well placed to take advantage of all the sunlight there is, but for many months in the winter season there is little sunshine, and he is compelled to fall back upon artificially produced ultra-violet light. He himself has devised a special form of mercury vapour lamp, which is well known in this country.

Up to recent years the treatment of the patients has largely consisted of the judicious use of actinotherapy combined with every agency which may help to improve the general nutrition, and especially to bring the skin itself into the healthiest possible condition. Professor Jesionek works on the theory that in the skin there resides the chief antituberculous defences of the body, and he employs light solely as a stimulus to the skin to make it produce fluids of high antituberculous value in large quantities. He sedulously avoids any suspicion of an inflammatory reaction, for that would mean that the skin had sustained injury, and, in consequence, diminution of its antituberculous power. In addition to light he also advocates the employment of other agencies such as exercise, exposure of the skin to fresh air and the use of cool baths—all for the purpose of improving the cutaneous condition. Locally he employs the Kromayer lamp, and does not despise the older methods of erasion and the use of chemical caustics. He does not, however, use the Finsen lamp, or its more manageable modification, the Finsen-Reyn. The chief reason is the great expense involved owing to the necessity of having a nurse in attendance the whole time for each patient, and money is very scarce in Germany at the present time. But the experiment which is now being conducted at this institution has nothing to do with light. About two and a half years ago Professor Jesionek began tentatively to employ in a few cases the dietetic treatment of lupus on the lines first suggested by Gerson, and subsequently developed by Bommer, Sauerbruch, and Hermannsdorfer. This originally consisted in the administration of an absolutely salt-free diet—that is sodium chloride-free. Such a diet being extremely unpalatable to many people, a special mixture of salts (excluding, of course, sodium chloride) termed "mineralogen" was given instead. In addition to their food the patients were given a teaspoonful of phosphorized cod-liver oil three times a day.

At the outset only a dozen patients were put on this dietetic treatment and at the same time the usual routine actinotherapeutic measures were continued. But, quite contrary to the professor's expectation these patients underwent remarkable improvement and since then more and more have been put on this dietetic treatment until at the present time all patients without exception are treated dietetically and the other more conventional methods of treating lupus have fallen more and more into the background. While all the patients are treated dietetically they are not now given quite the same diet as they were at the outset of this large experiment. The leading feature of the original Gerson diet was the complete absence of ordinary table salt, in the diet now given in the Giessen Hospital salt is still absent, but the essential feature of the regime at the present time is rather the fact that all the food is uncooked. The special "mineralogen" mixture is dispensed with, and latterly even the administration of cod liver oil has been discontinued, but the results of the diet are still excellent. These results are quite consistent with Professor Jesionek's theory of the incidence of tuberculosis. He is never tired of pointing out that tuberculosis is exclusively a disease of civilized man and domesticated animals. Both men and beasts living in a wild state are free from it, owing to the fact that their skins are able to produce antituberculous fluids in sufficient quantity to destroy at once any tuberculous bacilli with which they may come in contact. When civilized or domesticated this property is greatly diminished, and in consequence the man or animal becomes liable to tuberculous infection. The whole basis of the treatment of tuberculosis should be, according to Jesionek, the restoration of the skin to its natural state, with adequate power for the production of antituberculous bodies. It is exclusively with this object that he employs actinotherapy, baths, and exercises of various kinds. The new dietetic treatment falls in line easily enough with this theory. Men and animals living uncivilized and undomesticated existences, and consequently free from tuberculous troubles, eat their food raw, nor do they take salt with it. Consequently, he holds that the diet now administered at the Giessen Hospital gives a further opportunity for the patients to approach the conditions under which their skins may acquire once more their antituberculous properties to the fullest extent.

The practical side of the dietetic treatment of lupus is not without its difficulties. Owing to the fact that many patients find saltless food very dull, meals are kept to very small dimensions but given at frequent intervals, and there are no fewer than seven meals per diem. The food is of a mixed character (for it is uncertain whether the food of primitive man was animal or vegetable or mixed in character), containing a small quantity of meat, but fruits and vegetables form an important part. Eggs milk, and butter are also given freely. It need hardly be said that all smoked and salted articles of food are religiously eschewed. When the present writer visited the hospital he saw a number of cases of great severity and long standing which had resisted all attempts to cure them until they had been put on the dietetic treatment and which now had either completely recovered from the disease or at all events were within a little of that achievement. None of them had been dieted for more than two years, and most of them much less. At the same time their general health had been well maintained, and there had been a moderate increase in weight.

Professor Jesionek and his assistant Dr. Bernhardt have published a booklet on the dietetic treatment of lupus and the biology of nutrition which details their results up to January 1930.[1] Up to that time 341 patients had been treated but by now the number must have been greatly increased. They give very convincing illustrations of the benefit received by patients suffering from obstinate and widespread lupus, and there is no doubt that the possibility of the cure of lupus vulgaris by means of diet has been proved. Whether there is much need for those of us in this country who have charge of lupus cases to adopt this method of treatment is another matter and moreover it would be quite impossible to carry it out on out-patients as are most of our lupus cases. On the other hand it is undoubtedly worthy of study by those who are responsible for the public health of large districts and who maintain large hospitals containing many patients suffering from both lupus vulgaris and surgical tuberculosis (for the dietetic treatment of the disease applies also to the latter). The whole subject certainly deserves examination by the medical departments of the L.C.C. and other county councils who are responsible for the treatment of large numbers of tuberculous patients and into whose hands finally gravitate the most obstinate and difficult cases.

H. HALDIN-DAVIS

Scotland.

Vital Statistics for Scotland in 1929

THE seventy-fifth annual report of the Registrar-General for Scotland dealing with the year 1929, has just been published. The population of Scotland in the middle of the year is estimated to have been 4,894,032, which is 9,150 less than the estimated population of the previous year owing to the net emigration having been greater than the excess of registered births over deaths. The births registered during the year numbered 92,880, giving a birth rate of 19·02 per 1,000. This number is 3,942 less than the number for the previous year, and is the lowest recorded in any year since the introduction of registration in 1855. The maximum birth rate recorded was 35·62 in the year 1876. Up to the year 1893 the Scottish birth rate was always over 30 per 1,000, and from 1894 to 1914 consistently over 25. Since 1921, the rate has always been under 25 and since 1926 under 20. The Scottish birth rate compares favourably with that of England and Wales, which was 16·3 per 1,000, while that of Northern Ireland was 20·4, and that of the Irish Free State 19·8. The deaths registered during the year numbered 70,917, giving a death rate of 14·52 per 1,000. The number of deaths exceeds that of the previous year by 5,646, and the death rate, 14·52 per 1,000, is the highest Scottish death rate since 1922. In the preceding year the death rate was 13·34 per 1,000, the rise is attributed to a severe epidemic of influenza which occurred during the earlier months of 1929. The infantile mortality rate for the year was 86·8 per 1,000 registered births, which is higher by 1·1 than that of the previous year, but lower by 2·4 than the mean of the preceding five years, and lower by 4·2 than the mean of the preceding ten years. The only years in which the Scottish infantile mortality rate was lower were 1923, 1926, and 1928, when the rates were 78·9, 83·1, and 85·7 respectively. Previous to 1915 this rate was always over 100, and exceeded 130 on eight occasions. The number of centenarians whose deaths were recorded in 1929 was 14, of which 10 were verified. In the last twenty years 281 reputed centenarians have been recorded and their ages investigated with the result that the attainment of an age over 100 has been verified in 139 cases, disproved in 43, while in 99 cases confirmation could not be obtained.

Causes of Death

The 70,917 deaths registered in Scotland during 1929 included 35,386 males and 35,531 females. Compared with the figures of the previous year the excess of male deaths was 2,809, and of females 2,837. The total number of deaths exceeded that of any year since 1922, but was less than that registered in any year between 1863 and 1915. The death rate in the male population was 15·09, and in the female 13·99 per 1,000. With regard to age at death 12,201, or 17·2 per cent., were children of less than 5 years of age, 40·6 per cent. were persons between 5 and 64, while 42·2 per cent. were persons aged 65 and upwards. The number of deaths at ages under 5 was 345 less than in the previous year. The infantile mortality rate for the year among male children was 97·3 per 1,000 and among female children 75·7, the male infantile mortality rate exceeding the female by 21·6. Deaths from enteric fever during the year numbered only 18, which is the smallest number yet registered in any year. In 1865, which was the first year in which deaths from enteric fever were shown separately, these deaths numbered 1,048, and fell below 1,000 for the first time in 1883, since then they have been progressively diminishing. For the second year in succession no death has been registered as due to typhus fever in Scotland, and for the eighth consecutive year no death has been registered as due to small-pox. The number of deaths attributed to measles was 149, which is 856 less than in the previous year, 780 less than the mean of the preceding five years, and 900 less than the mean of the preceding ten years. This is the smallest number of deaths from measles registered in any year since 1855, the previous smallest being 512, which occurred in 1925. All the deaths with the exception of 4, were of children under 10 years of age. Deaths from scarlet fever numbered 109, which is the smallest number of deaths from this cause recorded since 1855. The number of deaths from whooping cough was 901, being 171 less than in 1928. Of the 901 deaths, all occurred among children under 10 years of age, with the exception of 4. Deaths attributed to diphtheria numbered 471—17 fewer than in the previous year. With the exception of 40, these deaths occurred among children under 10 years of age. Deaths attributed to influenza during the year numbered 3,435, giving a death rate of 70 per 100,000, which is the highest number of deaths from influenza in any one year since 1922, and 2,474 more than in the previous year. The number of deaths attributed to all forms of tuberculosis was 4,580, which is 142 less than that of the previous year, 519 less than the mean of the preceding five years, and 941 less than the mean of the preceding ten years. This is the smallest number of deaths from tuberculosis recorded since 1855, the previous smallest number being 4,722 in 1928. The maximum number of deaths from tuberculosis in Scotland was 13,027, which occurred in 1870. The number of deaths fell below 10,000 in 1888, below 8,000 in 1914, below 6,000 in 1921, and below 5,000 in 1926. Of the 4,580 deaths from tuberculosis, 3,288 were ascribed to tuberculosis of the respiratory system, 519 to tuberculous meningitis, 303 to tuberculosis of the intestines, 65 to tuberculosis of the spine, 40 to tuberculosis of joints, and 365 to tuberculosis in other sites. Deaths from cancer and other forms of malignant disease numbered 7,108—207 more than in the previous year, 381 more than the mean of the preceding five years, and 755 more than the mean of the preceding ten years. The death rate from this cause was 146 per 100,000, which is the highest death rate yet recorded, the previous highest being 141 in 1927 and 1928. The death rate from cancer is now more than twice as high as that from respiratory tuberculosis, and indicates a great change from the year 1879, when the death rate of respiratory tuberculosis was over four times as high as that of cancer. Of the deaths from cancer, 91·2 per cent. occurred among persons aged 45 and upwards. The commonest sites were stomach (857), intestines (537), rectum (239), liver (187), prostate (149), tongue (105), oesophagus (159), and lung (116). Deaths from diabetes numbered 616, and were 93 more than in the previous year, 115 more than the mean of the preceding five years, and 121 more than the mean of the preceding ten years. Of the 616 deaths 231 occurred in males and 385 in females. Deaths attributed to accidents of pregnancy and parturition numbered 638, which is 38 fewer than in the previous year. Of these, 221 were attributed to puerperal sepsis, this number being 13 less than in the previous year. These deaths were equivalent to a death rate of 6·9 per 1,000 registered births, which is 0·1 less than the death rate of the previous year.

Vaccination of Children

An appendix to the Registrar-General's report for 1929 deals with the vaccination of children born in Scotland during 1928, who should have been vaccinated during that year or during the first half of 1929. Of the 96,869 children born in 1928, 6,648 died before reaching the age of statutory vaccination (six months). Of the 90,221 children surviving, 58·13 per cent. were certified to have been either successfully vaccinated or reported to be insusceptible. Unvaccinated cases constitute 40·43 per cent., the majority of these children, or 33·91 per cent. of the total, were unvaccinated by reason of a declaration of conscientious objection on the part of the parents. The percentage vaccinated is 2·58 less than in the previous year. It is pointed out that after the passing of the Vaccination (Scotland) Act, 1907, the number of vaccinated children continued to diminish, reaching a minimum of 54·49 in the year 1918, in 1920, following an epidemic of small-pox, the rate rose to 70·54, and thereafter continued to fall again.

Conference of Cremation Authorities

At the ninth annual conference of cremation authorities, recently held in Edinburgh, Dr. A. A. Musson, medical officer of health for Liverpool, supported the suggestion that the statutory regulations for cremation and the certificates B and C should be included as part of the study of medical students in their last year of training.

in all universities and medical colleges Although most medical practitioners, he thought were in favour of cremation, it was advisable that medical students should be more precisely informed of its advantage and instructed in the proper filling up of the various forms This was done at Liverpool, where the medical students were taken round and shown the working of the crematorium It was difficult to persuade people to regard cremation as a serious proposition but he was of the opinion that the movement was making satisfactory progress Dealing with the question of the adoption of uniform standard forms by all cremation authorities, Mr J Dan Lasson said that in his experience doctors sometimes made mistakes in filling up the forms He suggested that certain short instructions should be printed in bold type, so that doctors might have them brought before their eyes at once A great deal of trouble and expense might be saved in consequence It was often very difficult to get any mistake made by a doctor rectified in the short time available between the receipt of the application and the time appointed for cremation If there was one standard type of instructions doctors would know exactly what they had to do In opening the discussion on cremation from the public health point of view, the chairman, Mr Murray A Phelps, LL B, said that between 4,000 and 5,000 deaths were registered every year without any medical certificate as to the cause of death Although the details of such cases were remitted to the coroner, there was urgent need for the revision of the rules affecting certification where burial was the method adopted Mr G Noble, representing the Cremation Society, emphasized that cremation was a matter of the utmost importance to the health of the living and ought to be more closely considered by the sanitary services In this connexion the proposal was made by another member that its regulation should be transferred to the Ministry of Health Among other subjects discussed was the attitude of undertakers towards cremation, and the reduction of fees in the case of persons insured under the national health insurance scheme A number of addresses were read at the conference, which included papers by Professor S A Smith of the University of Edinburgh on cremation and crime, by Rev Dr George Christie on the Church and cremation, and by Dr J J Jervis medical officer of health for Leeds, on public health authorities and cremation The proceedings concluded with a visit to the Glasgow crematorium by about forty of the delegates and their friends

Dundee Royal Asylum

The one hundred and tenth annual report of the Dundee Royal Asylum, including that of Dr Arthur B Dalgetty medical officer of the institution, states that 57 patients were on the register at the close of the year ended June 16th 1930 Of these, 20 patients were admitted including 15 voluntary patients and 5 under certificate Fifteen were discharged, and 8 died Of the 15 discharged 14 were voluntary patients most of whom had derived benefit from their stay in the hospital The report points out that the excess of voluntary patients over those certified indicates that full advantage is being taken of the method of voluntary entrance, and that it works in a very satisfactory manner

Royal Asylum of Montrose.

The report of the Royal Asylum of Montrose for the year ended May 15th, 1930 including the report of Dr C J Shaw, physician superintendent of the institution states that the number of patients on the register at the end of the year was 745 During the year 66 men and 64 women were admitted, while the number of discharges was 68 Of the latter, 43 patients left the institution recovered 12 relieved, and 13 not improved There were 78 deaths—38 of men and 40 of women—which gave a death rate, calculated upon the average number resident of 10 4 per cent The average age at death was 65 25 years Six of the deaths were due to tuberculous disease from which the patients suffered on admission Thirteen deaths resulted from diseases of the nervous system (one from general paralysis), and 33 from senile decay There were 44 voluntary patients resident at the beginning of the year, and 32—22 men and 10 women—were admitted In this year for the first time two voluntary patients were admitted chargeable to a parish, and the hope is expressed that this procedure will now be more largely adopted No change is reported among the service patients who numbered 31 altogether, including 5 officers As conditions predisposing to mental breakdown, heredity was noted in 44 instances alcoholic intemperance in 13 cases, in 7 cases the illness was stated to be due to financial and business worry, and in 5 cases to privation Only 2 patients with general paralysis were admitted during the year, which is the lowest number on record Thirty-one patients suffered from melancholia 12 from mania, 24 from dementia of various forms, and 17 from senile dementia

England and Wales

Home Ambulance Service.

In its report for the quarter ended June 30th, 1930, the Home Service Ambulance Committee of the Order of St John and the British Red Cross Society (12, Grosvenor Crescent S W 1) directs attention particularly to that branch of its work which is concerned with the care and transport of the sick The extension of institutional treatment which has followed the improvement of hospital facilities and their adaptation to the requirements of those who can afford to pay for the service they render, has emphasized the need for unremitting effort in maintaining the efficiency of this department As the committee remarks, a hospital or well-equipped nursing home is a doctor's workshop, where repairs can be most effectively carried out, but much of the success of institutional treatment in serious cases of illness must depend upon the skilful conveyance of patients from their homes During the quarter the number of patients carried in ambulances was 28,204, bringing the total number conveyed since the organization of the service up to 901,451 The figures for road casualties dealt with during this summer are not yet available, but over 10,000 patients are reported to have been treated by members of the Order and Society at their roadside first-aid stations last year This estimate refers mainly to accidents that happened during week-ends and holidays While continuing to urge the provision of first-aid facilities in every town and village in the country the committee recognizes the good will and devotion demanded of its voluntary roadside workers who spend many tedious hours in waiting for accidents to occur It suggests that with accumulating experience units will be able to adjust their schemes to local conditions so as to provide the most useful service in their power without unnecessary expenditure of energy

Post-graduate Work in Manchester

In 1927 the University of Manchester appointed a medical post-graduate committee with the object of arranging free courses and of co-ordinating the not inconsiderable amount of work already done by the Manchester Hospitals The trial period of three years has now elapsed, and, with this experience of the past to help, courses have now been arranged for the year 1930–31 It has been learnt that while Manchester does not attract visitors from outside there is a definite demand for special work by those in Government and other services in the district and also that practitioners desire isolated lectures in subjects of interest The general trend is for the Royal Infirmary to specialize in student teaching and for the Ancoats Hospital to afford post-graduate clinical work At the latter hospital clinical cases laboratory demonstrations and x-ray examinations will be available each Thursday in term time at 11 a m Clinical assistantships including one in radium therapy are available at some of the special hospitals Part-time courses will be given during the year in ophthalmology, dermatology, minor operations (Salford Royal Hospital), and bacteriology The Royal Infirmary will hold its usual courses of afternoon lectures at 4 15, those on Tuesdays will be given by the honorary staff, those on Fridays will be of a more technical nature,

given by outside practitioners Among these are Dr Lane on lead, Mr W Woods, F R C V S, on the veterinary side of tuberculosis, Dr David Blair of the Prestwich Mental Hospital on mental defect and exhaustion, and Mr Gordon Whitehead on gonorrhœa

On Friday, November 7th, Dr E W Barnes, Bishop of Birmingham, will give the seventh Lloyd Roberts Lecture, on heredity and predestination This will be given in the Physiological Theatre of the University, at 4 15 p m

The London Hospital

In the absence of Lord Knutsford, Sir William Paulin, treasurer of the hospital, presided over the quarterly general court of the London Hospital, which was held on September 3rd According to the statement presented by Mr Elliot, now house governor in succession to Mr E W Morris, the hospital waiting list stood at 1,100, in spite of the fact that there was a slight falling off in the daily number of patients On an average three emergency operations were performed each night The children's out-patient department was nearing completion, and would shortly be ready for occupation The cost of the work—namely, £5,714, had been covered by the sum of £4,386, which had been contributed in response to a special appeal by Lord Knutsford, and a cheque for the balance of £1,328, which had been sent to the hospital by Mrs C C Croft The diagnostic apparatus in the x-ray department was of an obsolete type, and was being replaced by the most efficient apparatus at present available It would now be possible to take radiographs of the chest at a distance of 6 feet, and with a tenth of a second exposure, thereby reducing distortion to a minimum The apparatus for x-ray treatment was also being replaced, and arrangements were being made to accommodate it on a better site Towards the total cost of the new equipment—£6,375—the hospital had £4,694 in hand A new heart department was to be built next to the west wing, the General East End Tradesmen's Association having generously undertaken to cover the cost, which would amount to £6,500 Also under consideration was a project to build a massage and electrical department on a site at the west end of the out-patient department, in order that the two departments, at present some distance from each other, should be in close proximity Reference was made in the report to the investigations by which Drs S P Bedson and G T Western had shown psittacosis to be due to a filterable virus

Correspondence.

A LABORATORY DIAGNOSTIC SERVICE

SIR,—In your issue of September 13th (p 418) Dr W G Willoughby makes a powerful case for the extended provision of laboratory methods of diagnosis, and urges that a service for this purpose should be established in connexion with the public health departments of the country Of the need for the general provision of such a service there are no two opinions, whether it is desirable that it should be developed as a part of the public health service is open to debate

The public health service plays a valuable part in the control of the mass health, its officers have special knowledge in this direction and special means at their disposal to this end The health of the individual is dealt with by a different service, with its own officers (the medical practitioners of the country) and its own institutions, the most important of which are the great voluntary hospitals so widely spread throughout the land The voluntary hospitals focus the medical activities of their own districts and of the country as a whole, and it would appear that it should be through them that such a pathological service should be conducted No doubt in the future the municipal hospitals will also be able to take a part in this work

The need for some general diagnostic service, open to those unable to pay large fees or any fees at all, is mainly felt by those medical practitioners working under the National Health Insurance Acts For those able to pay even moderate fees there is no difficulty in providing all the laboratory facilities necessary It is the patients of the panel doctor who are most often unable or unwilling to pay laboratory fees The national health insurance system covers an immense number of individual patients, and if dependants come to be included the system will cover the bulk of the population, on the face of it it would appear that it is as a part of the national health insurance system that any general service for the provision of laboratory facilities should be developed

Dr Willoughby does not suggest that it is desirable that such a diagnostic service should be run in connexion with laboratories already established by the public health authorities He recognizes that there are "important reasons for the employment of the best pathologists" because "they can frequently assist the clinician in the interpretation of results" This is a point of the utmost importance The work of a public health pathologist and that of a clinical pathologist differ widely both require special knowledge, but that special knowledge covers entirely different fields The avenue of approach in the laboratory investigation of a case and skill in the interpretation of the results of such investigations can only be learned by long experience gained in close contact with individual patients, and such experience can only be satisfactorily acquired in the wards and pathological department of a general hospital

The pathological departments attached to the general hospitals throughout the country would then appear to be the ordained places for the development of such a service Most of the larger voluntary general hospitals already possess well-equipped pathological departments with experienced and efficient staffs Those which so far have been unable to afford the cost of maintaining such departments would speedily establish them could they be assured of a steady flow of paid work which would assist in their maintenance

The pathological department, on account of its diagnostic work, is one of the most important of the special departments of the modern hospital, it is, further, unusual to find a pathological department in which some effort at research is not being made A laboratory diagnostic service working through the pathological departments of the general hospitals would therefore not only in itself be the means of advancing the standard of medical practice throughout the country, but would also serve materially to increase the efficiency of the general hospitals

It is the belief of this association that such a service could be conducted in this way, and that it would be of great benefit to the community All those interested in this very important question must be indebted to Dr Willoughby for having so forcibly drawn attention to a crying need —We are, etc,

J G GREENFIELD, M D, F R C P
Vice-President

The Association of Clinical Pathologists

Wolverhampton, Sept 15th

MASSIVE COLLAPSE OF THE LUNG

SIR,—Dr J M Woodburn Morison, in his British Medical Association Lecture delivered to the Dundee Branch on April 29th, and published in the *Journal* of August 16th (p 237), concludes that massive collapse of the lung is due to a spasmodic contraction of the musculoreticulum of the organ, the function of this musculature being deranged by various causes acting upon the vagal and sympathetic innervation directly or reflexly He quotes Rose Bradford, who holds that there is a reflex stimulation of constrictor nerve fibres to the muscles of the bronchioles He also mentions Sante, who believes that such stimulus is derived from a toxic condition, from an interference with the nervous supply of the vagus, and from abdominal or chest injuries or operations He regards the acute dilatation of the stomach which may follow a laparotomy as an analogous condition

In a previous communication (*Journal*, 1927, vol II, p 985) I suggested that such phenomena of violent aberration from the normal on the part of the trophic nerve mechanism are due to reflexes or toxins influencing subjects

who are hypersensitive and exhibit the phenomena of anaphylaxis. Such a hypothesis alone can explain the occurrence of these conditions in some subjects and not in others. The causal factors are repeated in case after case, only some patients develop these phenomena.

Why do some old people with advanced arterio-sclerosis suffer from attacks of acute pulmonary oedema, a condition so fulminating that it could be regarded as an acute and violent outbreak of trophic mania? The inciting cause is probably the exposure to cold during undressing and on getting into bed between cold sheets. Why do some of us sneeze and afterwards develop a coryza on exposure to cold air, the sneezing being due to an abnormal hyperaemia of the nasal mucous membrane as the result of a nerve reflex from the cold? Probably the same reflex starts a pneumonia. The nerve reflex explains the upset of the trophic reflex but why does such an abnormal result threatening and often causing death ever occur? Because the underlying condition of hypersensitiveness is present.

In the *Annals of Surgery of Philadelphia* May, 1930 Drs. Wilmer, Cobe and Lee report the results of an investigation into the incidence of allergy and asthma in a group developing post-operative atelectasis. They prove to their own satisfaction that such incidence undoubtedly occurs. This confirms my contention, which was arrived at on purely theoretical grounds but the truth of which I have proved by continuing to give a desensitizing dose (0·3 gram) of peptone fourteen hours before every laparotomy to the patients operated upon at our War Memorial Hospital. The results have been startling and continue to be so.—I am, etc.,

Welton Mowbray, Sept. 14th. MONTAGUE DIXON.

RADIUM THERAPY

SIR,—My apologies are due to Dr. Stanley Melville (September 13th, p. 448) for the omissions he took exception to in my lecture on the technique of radium therapy to-day. No slight was intended either to the radiologist, to the physician, or to the pathologist. These three must form such an important part of any radiological team that their inclusion was rather taken for granted. The biologist and physicist and other more special laboratory workers do, I fancy, need mention, as though they are just as useful they are perhaps not quite as obvious to the general practitioner, to whom the lecture was delivered. Modesty should have prompted me to omit the surgeon.

In reply to Dr. Howitt Hastings, I would say that almost any form of radium will undoubtedly cure rodent ulcer, and for this treatment, and for this only I fancy the metal plaque survives. As to the use of radon, we really seem to be quite in agreement. For any service, State or otherwise, run in connexion with a radon producing establishment has great advantages.—I am, etc.,

London, W.1, Sept. 22nd. DUNCAN C. L. FITZWILLIAMS.

PERFORATING DUODENAL AND GASTRIC ULCERS

SIR,—To wait for a few hours till shock passes off may be all right under the immediate eye of Mr. Basil Hughes (September 20th, p. 497), but it is dangerous treatment to broadcast, as it might lead to a mistaken policy in other ways—the diagnosis, consultation, removal, etc. For shock give morphine, up to 1/3 grain hypodermically, and operate *at once*. But the shock may be slight, and morphine not required. The shock varies from *nil* to instant death. I thought all that was settled in the nineties. Needless to say morphine is never to be given if the diagnosis and necessity to operate at once are not agreed upon by all concerned, otherwise a dangerous delay may seem justified, so altered by the morphine is the picture (as in other critical states).

Statistics of mortality are not informing unless they embrace the interval of time between perforation and operation. Lundie, early in the nineties, spoke of that interval as "eloquent of the dangers of delay." The mortality is determined, granting the practically equal skill of the modern surgeons who operate on these cases, by (1) the time between perforation and operation, (2) the time since the last meal, (3) the site and size of the perforation, and the second and third factors determine (4) the amount of extravasation. I think these conditions far outweigh in their influence on mortality the difference between habitual ether administration and spinal anaesthesia, with or without local anaesthesia.

I cannot follow Mr. Hughes in his remarks about cigarette smoking. Between thirty-five and twenty-five years ago when I encountered more of these cases than I do to-day in general practice, women were not smokers, and my impression (possibly wrong) is that there are fewer cases in this "tobacco age" than there were formally. It was in 1895 that I saw my first case of perforated stomach, and in the skilful hands of the late Mr. Kennedy Dalziell it became, I believe, the first case recorded in Glasgow of recovery after operation.—I am, etc.,

Glasgow, Sept. 22nd. R. O. ADAMSON, M.D.

CRETINISM WITH GOITRE

SIR,—I have for some time tried to obtain information as to the existence in Great Britain at the present time of cretinism associated with the presence of a goitre. Several kind correspondents from those regions where goitre is endemic have written to me pointing out the rarity of goitrous cretinism in their own districts but I have been unable up to the present to find out whether in fact any cases illustrative of the condition are now to be found. If any of your readers could send me particulars of such a case, preferably with a photograph showing the condition of the neck, I should be most grateful.—I am, etc.,

6, Harley Street, W.1, Sept. 26th. CECIL A. JOLL.

PYREXIA OF UNCERTAIN ORIGIN

SIR,—During the last few weeks there have been occurring in this district cases of illness which appear to me to present some novel features, and I should be interested to hear whether other practitioners have come across similar cases.

The illness begins somewhat suddenly with severe headache, usually frontal, sometimes accompanied by vomiting. There is considerable prostration, and pyrexia of 100–103° F. Often photophobia is present. After a few days' rest in bed the headache lessens and the fever subsides, and the patient is usually convalescent within a week. There is one sign the recognition of which I owe to a colleague, Dr. F. P. Halkyard, that I have found almost always present—namely, pain in the dorsal spine on flexing the head. In most cases there is also definite cervical rigidity. Kernig's sign is doubtful or absent. In some cases I have found the tendon reflexes, especially the knee-jerk, to be somewhat exaggerated.

I write this short note in the hope that some light may be thrown on the nature and cause of the condition. Is it influenzal? If so the absence of cases of the usual catarrhal type at the present time appears remarkable. Some of my cases have had a rather slow pulse, 40–50 during defervescence and some have had "girdle pain" in the upper abdomen. There have been several instances of infection from one case to another, and apparently the incubation period is short—twenty-four to forty-eight hours. There have been no ocular symptoms apart from the photophobia and no local pareses have been observed. In none of the cases seen so far has the illness been sufficiently severe or prolonged for lumbar puncture to be justified.—I am, etc.,

W. HOTSON PALMER, M.B., B.Chir.

South Lowestoft, Sept. 15th. L.R.C.P.

THE CORONER

SIR,—It is useless to waste time over this survival from the early Middle Ages. He and his inquests are equally obsolete. The recent Coroners Act has only made the position of the wretched man worse than ever. The legal coroner knows no pathology, the medical coroner knows no law, and woe betide the amphibious coroner who has been called to the Bar but has never practised in court, with an opponent at his side to trip him up if he makes a slip in the law of evidence, and a judge before him who may retort to his efforts, "Mr. S., I have been forty years in

the law, and if what you say is right I have yet to learn my business" I heard this remark in the High Court Most of the trouble in the coroner's court comes from ignorance or disregard of those elementary rules of evidence which every practising barrister has at his fingers' ends, and which no amount of reading can ever implant in the non-legal mind If the coroner was abolished entirely, and his duties transferred to the police magistrates, who could sit, like county court judges, with medical assessors there would be an end of the conflicting jurisdiction which the recent Act has brought into greater prominence than before It may surprise many coroners to hear that opinion is not evidence except in the case of experts A regional pathologist would be such an expert, and his opinion would be evidence

Cross-examination should be directed to putting one's client's case but in the formless court of the coroner there are no parties no issues, no joinder of issue, no counsel, and only too often no law It is useless to tinker with this hopeless official, who has been the butt of the satirical ever since Shakespeare's grave diggers in *Hamlet* (Act V, sc 1) "Is this law?" to Blackstone there were endless complaints of the incompetence of the coroners —I am, etc,

Lewisham Sept 16th GEORGE JONES

NECROPSIES IN GENERAL PRACTICE

SIR,—There are two schools of thought on this matter the one holds that the performance of post-mortems by general practitioners is undesirable because it leads to inefficient work—that is, that the G P is not competent to perform necropsies—the second holds that practitioners are competent, and that they ought to hold on to this work because, if they do not, the time is not far distant when there will be no work left for which the G P will be held to be competent This discussion is a particular example of the general problem which faces the profession at the present time On the one hand increasing efficiency is required in all medical work, while on the other it is being realized that specialism, if it is accompanied by the elimination of the family practitioner, must seriously impair the efficient care of the health of the people There seem to be two lines along which the profession can strive to develop so that the family or general practitioner may be saved from extinction, while at the same time that increase of efficiency which is essential may also be attained These changes take years and come about almost unnoticed Then general direction ought not, however, to be left to blind chance It should be purposively pursued by those members of the profession who are concerned The first change is towards a modified specialization amongst the general practitioners In each area certain practitioners ought to acquire special experience in one of the special branches—for example, pathology One or more of them should be given the status of a local appointment (as is done for the factory surgeonship) This is already done in pathology in practice to some extent, although it is not formally recognized This pathologist ought to be definitely linked up with the pathology department of the nearest hospital The second and, in my opinion the more important change is for the general practitioners to take more thought of the extension of their sphere of activity, rather than to try to hold back changes in the nature of their work, changes which are inevitable in any case This extension of the sphere of the G P cannot, and should not, be expected to be accomplished in a year or two The chief lines of this extension are concerned with the prevention of disease and the study of it in its early stages I know I am flogging a well-thrashed horse, but the trend of the present discussion convinces me that still more beating is indicated What seems to be most necessary is a slightly changed attitude of mind, on the part of the profession, towards the possibility of making up lost ground which the advance of the science—if not of the art—of healing has made inevitable Having mounted my hobby-horse I could ride after—I am etc,

Pitch Sep 20th HOWARD E COLLIER

SIR,—Most general practitioners will freely admit that they dislike performing post-mortem examinations because the process is carried out in private houses is distasteful and unpleasant, but more because the general practitioners who have not made a special study of morbid anatomy and post-mortem methods know that they do not derive all the information they should from the examination How can they be expected correctly and accurately to interpret post-mortem appearances when the opportunities of making such examinations come their way so fortuitously, so seldom, and in such discouraging circumstances? A necropsy—especially for medico-legal purposes, with its ensuring bacteriological and chemical inquiries—may require as much planning as a surgical operation, and its successful accomplishment calls for a specialist just as much as the latter does The letter of Dr Binns (September 13th, p 449) does not make out a case against a specialist in post-mortem work, but only for the intrinsic interest of post-mortem findings

The opportunity was missed years ago Those responsible for framing the Insurance Act made elaborate preparations for advice (A), visits (V), and certificates (C), and for ladling out gallons of medicine They even went so far as to discourage peppering the patient with pills, but encouraged the keeping of records Had they put aside a few pence per head for a pathological service many of these medical records, which now are often merely the data of unsolved problems, would have received a welcome amount of illumination and have made an immense contribution to knowledge The general practitioner who was genuinely in search of the truth could be present at a post-mortem examination made by an expert, and could learn more in an hour in the mortuary than he could in days spent in a library Any general practitioner so minded could qualify as a specialist pathologist and ask to be put on the panel of pathologists The coroners would be delighted Their troubles would be lightened A non-medical coroner quite recently told me with glee that he had discovered a young medical man with a zest and enthusiasm for post-mortems, and that, for that area at any rate, he knew how to allot the work in future —I am etc,

September 15th URBANUS

A VITAL REACTION IN THE DENTAL ENAMEL

SIR,—I have noticed in your issue of September 13th the remarks on the possibility of a vital reaction in the dental enamel, which were in connexion with the communication made by Mr Evelyn Sprawson before the Royal Society The notes regarding the work of the late Mr Howard Mummery (*British Dental Association Journal*, May 1st, 1926) appear to me to be inaccurate, and anyone who had actually examined the slides which he prepared could not help being convinced that there was every probability of the reaction taking place to damaged enamel, and moreover, I do not think that his assertions have ever been proved to be inaccurate Mr Sprawson has made a distinct gain in our knowledge of the reaction of the enamel to injury, and I consider that he shows that the enamel makes an effort to repair the lesion, which is after all only what one would expect it to do Your communication appears to me to unnecessarily adversely criticize Mr Sprawson's work and that of the late Mr Howard Mummery, both of whom have put forth evidence that enamel has reparative power, and I think everybody who looks carefully at the actual sections would be convinced of that fact —I am, etc,

Birmingham Dental Hospital, Sept 16th C HOWKINS

OCCIPITO-POSTERIOR POSITIONS

SIR,—With regard to occipito-posterior positions among races that habitually squat, my experience is that there are as many cases in proportion among the natives of South Africa and India as among those races that adopt European or Chinese habits—that is, as regards chairs Another popular idea is that the savage woman does not suffer in childbirth, I have found that she does, and also that the death rate in childbirth is very high among the less advanced peoples —I am, etc,

Libode, Pondoland, Aug 21st JOHN EVANS, M D

Obituary

SIR NEVILLE HOWSE, V.C., K.C.B., K.C.M.G.,

Late Director General Australian Army Medical Service

MAJOR GENERAL SIR NEVILLE REGINALD HOWSE, V.C., K.C.B., K.C.M.G., late Australian Army Medical Service, died in a nursing home in London on September 19th, aged 67. He was the second surviving son of the late Alfred Howse, M.R.C.S., of Stogursey, Somerset, was educated at Fulland's School, Taunton, and at the London Hospital, and took the M.R.C.S. in 1886 and the L.R.C.P. Lond. in 1887. Subsequently he took the F.R.C.S. in 1897, and in 1919 received an honorary F.R.C.S.Ed. After qualifying he went to Australia where he practised for some years. In 1899 he went to South Africa with the New South Wales forces, and in July 1900, won the Victoria Cross for going out under a heavy cross-fire and bringing in a wounded man during the action at Vredefort. During the South African war he took part in operations in the Transvaal and Orange River Colony, including the actions at Johannesburg, Pretoria, and Diamond Hill in June, and those at Bethlehem and Wittenberg in July, 1900, and gained the Queen's medal with six clasps and the King's medal with two clasps, as well as the V.C. He left South Africa with the rank of major, and returned to Australia.

When the great war began in 1914 he was promoted to lieutenant-colonel, and accompanied the Australian Expeditionary Force which took over German New Guinea, as principal medical officer. He then went with the First Australian Division to Egypt, being promoted to colonel and appointed A.D.M.S. to the division. In that capacity he made the medical arrangements for Anzac in Gallipoli, and for his services there was mentioned in dispatches in the *London Gazette* of August 5th, 1915, and received the C.B. In November, 1915 he was promoted to surgeon-general and director of the Australian and New Zealand Medical Services, and shortly after was made director-general of the medical services of the Australian Imperial Forces, holding that position to the end of the war. He was created K.C.B. in 1917, and K.C.M.G. in 1919. After the war he continued to hold the post of director-general of the Australian Army Medical Services till 1922, when he retired. In the same year he entered the Commonwealth House of Representatives, and subsequently held office, first as Minister for Defence and Minister for Health, and, later, as Minister for Home and Territories. He was one of the Australian representatives at the Fourth Assembly of the League of Nations.

In April 1919, the British Medical Association held a special clinical and scientific meeting in London the purpose being to set forth the work done during the war and to secure the presence of leaders of medical and scientific work in the forces before they returned to their civilian duties in different parts of the world. Sir Neville Howse, at that time D.M.S. Australian Imperial Forces, was a member of the general committee which organized the meeting, and took part in the proceedings. At the banquet in the Connaught Rooms, on April 10th he responded to the toast of the Oversea Medical Services.

In 1905 he married Evelyn, eldest daughter of Mr. C. de Vial Pilcher of Newstead, Orange, and had two sons and three daughters.

The funeral service was held at *All Souls' Cemetery, Kensal Rise*, on September 23rd. The Bishop of New Guinea officiated and the pall-bearers were the High Commissioner for Australia, Mr. S. M. *Bruce*, Sir Hugh Rigby, Mr. T. P. Dunhill, Mr. T. Trumble, and Dr. Lewis Smith. The Royal College of Surgeons of England was represented by Mr. C. H. Fagge, Vice-President, and the London Hospital Medical College by Professor William Wright.

ROBERT WILLIAM MacKENNA, M.D.,

Consulting Dermatologist, Liverpool Hospital for Cancer and Skin Diseases; Dermatologist to Liverpool Royal Infirmary

DR. R. W. MACKENNA, who died on September 21st, was a son of the Manse, having been born in Dumfries in 1874, the son of the Rev. R. MacKenna, minister of Martyrs Church. The dominating influences in his early years were clearly manifest in his later life and work.

Robert William MacKenna was educated at the Dumfries Academy and later at the Royal High School, Edinburgh, from which he passed to the University in that city where he took the M.A. degree in 1896. Thus early he gave evidence of his wide outlook on medicine, he took part in the various undergraduate activities and held responsible positions in many student organizations. He graduated M.B., Ch.B. in 1893, being one of the most prominent students of his year, and in 1908 proceeded M.D. At the close of his student career he visited the great medical centres on the Continent, and on his return settled in Liverpool. For some time the development of a general practice occupied his time, but he always had an interest in dermatology, and when the appropriate time came the change was made and his work became confined to this specialty.

He was appointed dermatologist to the Royal Northern Hospital and later to the Royal Infirmary, Liverpool, he was lecturer in dermatology at the University of Liverpool and he held also consultant positions in connexion with various other institutions. He never spared *himself* at work, but always gave of his best. He wrote a textbook on dermatology which is widely known. For his students, as for his patients, he could never do too much; he took a personal interest in the welfare of each one. To his *patients it may truly be said that he gave his life*; the conscientious thoroughness in all items of treatment which he meticulously observed particularly in the early days of employment of remedial methods at first incompletely understood cannot but have taken its toll of a worker whose day of leisure were few and far between.

In the war he served abroad with the rank of captain R.A.M.C. (T.F.). During this period he developed a new activity, which was to prove a most engrossing hobby to himself, as well as a source of enjoyment to a very large

circle of admirers Always keenly interested in literature, and a ready speaker with good command of language, experience in the war stimulated him to address a larger audience than could be approached by mouth, and in his books *Adventure of Death* and *Adventure of Life* he put before the public studies which immediately made a strong appeal He followed up these productions with a series of novels dealing with Scottish characters, and the beauty of expression, humour, and clear, brave idealism in them at once commanded success As editor of the *Liverpool Medical Journal* he did yeoman service, and he filled with distinction many important posts in the Liverpool Medical Institution, and only his untimely death deprived him of the very highest of these He was a member of the British Medical Association, secretary of the Section of Dermatology at the Annual Meeting in Liverpool in 1912, and vice-president of this Section at the Annual Meeting in Nottingham in 1926

Always a keen churchman, the Scotch Church in Liverpool owes much to him, an ardent Scot, the St Andrews and Burns Clubs will miss sorely his support and presence He was charitable by nature, supporting many benevolent funds, and helping many acquaintances out of personal difficulties He was a successful doctor, a dermatologist of great repute, a highly esteemed citizen, and a prominent speaker and writer He was in the best sense of the term a doctor of the old school—a physician respected and beloved by patients, students, fellow doctors, and all who knew him

A D F

THE LATE PROFESSOR MacILWAINE

PROFESSOR E B C MAYNS (Belfast) writes

Professor MacIlwaine's tenure of the chair of materia medica and therapeutics at the Queen's University of Belfast corresponded to a time of transition between the older teaching and the new Soon after his appointment he visited a number of well-known universities in England and America, and made a study of their methods of teaching He became convinced that the best foundation for the art of treatment is a thorough training in pharmacology and he recognized the unwisdom of trying to teach advanced therapeutics to students who have as yet little clinical experience Broad-minded far-seeing, and free from personal ambitions, he was well fitted for the task of organizing his department to fulfil modern requirements—a task which in spite of failing health, he carried to a successful issue

EDMUND HENRY HOWLETT, C B E, F R C S, who died on September 8th, was the son of General Sir Arthur Howlett, K C B He received his medical education at King's College Hospital, and was house-surgeon there from 1877 to 1888, the following year being appointed assistant demonstrator of anatomy, London Hospital Medical College He left London to take the post of resident surgical officer at the Manchester Royal Infirmary, after which, in the early eighties, he settled in Hull, where he was then the only F R C S He was appointed honorary assistant surgeon at the Hull Royal Infirmary as soon as a vacancy was made by the death of Dr King, and in 1897 became full surgeon, retaining this position until 1914, when, in accordance with the age limit fixed by Royal Charter, he became consulting surgeon On the discovery of *x* rays he took up their study with enthusiasm, all his spare time for several years being devoted to experimental research, in which he displayed unparalleled perseverance and patience He was appointed radiologist to the Hull Royal Infirmary, and held this post until eight years ago, when he was succeeded by Dr J F Bannon He was a member of the board of management of the Infirmary for twenty-two years, and for a long period was chairman of the standing medical committee For many years he was medical officer to the G P O and to H M Prison at Hull, and at his funeral four of the warders acted as bearers In his younger days he was an enthusiastic football player and athlete, in middle life his only relaxation seemed to be the study of *x* rays, with an occasional day's shooting, but during the past ten or fifteen years he developed his latent artistic talents and produced some excellent work in portraiture and seascape A man of the highest integrity his character may be well summed up by saying that he was "a fine old English gentleman" He leaves a widow and two sons

DR WILLIAM BURTON MARSHALL, who died on August 29th, after an illness of more than a year, was born in 1881 and received his medical education at Cambridge and Liverpool He obtained the diplomas M R C S, L R C P in 1906, and graduated B Ch in 1908 and M B in 1912 After acting as house surgeon in the gynæcological wards of Liverpool Royal Infirmary, and clinical assistant at Hoylake Lodge Asylum, he commenced general practice in Norwich in partnership with Dr Parkinson Bush Soon afterwards he was appointed honorary anæsthetist to the Norfolk and Norwich Eye Infirmary, and for many years he was physician to the Jenny Lind (Children's) Infirmary He took great interest in the working of the national insurance scheme, and was for several years chairman of the Norwich Panel Committee He was a member of the British Medical Association, and served on the Norfolk Branch Council During the war he was at first attached to the 1st Eastern General Hospital Cambridge, he later acted as adjutant in a hospital at Wimereux, and attained the rank of major R A M C T He leaves a widow and two children A colleague writes The death of Dr Burton Marshall will be felt as a great personal loss, not only by his relatives and friends, but also by all his colleagues and patients He had a most lovable disposition, and was a charming companion A well-read man, he was a fluent speaker and a versatile conversationist, full of wit, and quick at repartee

The death took place suddenly at Nairn, on September 8th, of Dr ROBERT MACKENZIE Dr Mackenzie was a native of Edinburgh, where he graduated M B, C M in 1883, proceeding to the M D degree in 1887 He was also a Fellow of the Royal Society of Edinburgh For a few years after graduation he practised in Edinburgh, and afterwards went to Nairn, where, at the time of his death, he had been in practice for some thirty years The death was very sudden, and occurred on the Nairn Golf Course

Medical News.

THE annual dinner of past and present students of University College Hospital will be held on Friday, October 17th, at 7 for 7 30 p m, at the Hotel Victoria, Northumberland Avenue, W C Mr Herbert Tilley will be in the chair Tickets (12s 6d) should be obtained from the dinner secretary, University College Hospital Medical School, Gower Street, W C

THE formal opening of the new session at Charing Cross Hospital Medical School will take place on Saturday, October 4th, in the hospital, at 4 30 p m, Dr J M H MacLeod will present the prizes At 8 p m that day the annual dinner of past and present students will be held at Gatti's Restaurant, with Mr E B Waggett in the chair There will be a special post graduate course on October 4th and 5th, the programme includes clinical lectures on such subjects as minor operations in general practice, disorders of the menopause, common skin diseases, ante natal supervision, and the diagnosis and treatment of glycosuria, renal pain, and gastric disorders

THE presentation of medals and prizes in the University of Birmingham Faculty of Medicine will take place on Monday, October 6th, at 5 p m, in the Medical Lecture Theatre, Edmund Street An address to students will be given by Emeritus Professor Priestley Smith, LL.D, F R C S. Tea at 4 15 in the University Club

AT the London (Royal Free Hospital) School of Medicine for Women on Wednesday, October 1st, at 3 p m, the prizes for the session 1929-30 will be presented, and an address will be delivered by Miss M. M Chadburn, M D, B S

THE introductory address at the University of Durham College of Medicine, Newcastle upon-Tyne, will be given by the Bishop of Durham, visitor of the University, in the examination hall of the college, on Thursday, October 9th, at 4 15 p m The title of the address is "The genesis of the physician's ideal"

THE prize distribution at the Royal Dental Hospital of London School of Dental Surgery will be held on Thursday, October 2nd at 8 p.m., at Leicester Square, W.C.2. Sir John Rose Bradford, P.R.C.P., will preside and give an address to the students and their friends.

DR. I. LANGDALE KELHAM of Roehampton Hospital, will lecture at the London (Royal Free Hospital) School of Medicine for Women on Monday, October 6th, at 5 p.m. on "Artificial limbs." The lecture is open to all graduates and clinical students of the school.

THE inaugural address at Westminster Hospital Medical School will be given in the board room of the hospital by the Rev. Dr. J. Scott Lidgett, Vice-Chancellor of the University of London, on Wednesday, October 1st, at 3 p.m. under the chairmanship of Mr. Walter G. Spencer. The annual dinner of past and present students will be held at Grosvenor House, Park Lane, on the evening of the same day, at 7.30, with Dr. S. Ernest Dore in the chair.

A COURSE of ten lectures on "Contraception and allied questions" will be delivered in the lecture hall of the Royal Institute of Public Health on Tuesdays at 4 p.m., from October 9th to December 11th, inclusive. The lecturers include Dr. C. Killick Millard, Dr. C. P. Blacker, Dr. Maude E. Kerslake, Mr. Harold Chapple, Dr. F. J. McCann, the Rev. Dr. A. Herbert Gray, Dr. Marie C. Stopes and Mr. Alfred Coodman. Admission is free but is restricted to members of the medical profession and to senior medical students. Particulars of the lectures may be obtained from the secretary of the Institute, 37, Russell Square, London, W.C.1.

THE course of nine lectures and demonstrations on tropical hygiene and medicine for prospective settlers arranged by the County of London Branch of the British Red Cross Society will begin on October 1st. Particulars may be obtained from the secretary of that branch, 27, Grosvenor Place, S.W.1.

A COURSE of lectures on the prevention of accidents, disorders and disease will be delivered at the Royal Institute of Public Health (37, Russell Square, W.C.1) on Wednesdays at 4 o'clock, from October 15th to December 17th. The lectures are intended primarily for the fellows and members of the Institute, but others interested in medico-sociological problems are invited to attend.

THE annual general meeting of the Medical Defence Union will be held at the offices (49, Bedford Square, W.C.) on Thursday next, October 2nd, at 4.30 p.m.

THE psychological section of the Medical Women's Federation will hold its annual conference on Saturday, October 18th, at The Lawn, Lincoln.

THE annual general meeting of the Medical Sickness Annuity, and Life Assurance Society will be held at the First Avenue Hotel, High Holborn, W.C.1, on Wednesday, October 8th, at 4.30 p.m.

THE Fellowship of Medicine announces that there will be a special post-graduate course in medicine, surgery and the special departments at the Metropolitan Hospital from September 29th to October 11th, occupying the whole of each day from 10.30 a.m. to 5.30 p.m. There will be daily pathological demonstrations. A course in diseases of the ear, nose, and throat to be held at the Central London Throat, Nose and Ear Hospital, Gray's Inn Road, from October 6th to 31st, will comprise clinical, operative and pathology classes; the clinical part may be taken alone or in conjunction with one or more of the other classes. There will be a course in gynaecology at the Chelsea Hospital for Women, Arthur Street, from October 13th to 24th, consisting of lectures and demonstrations in the operating theatre. An evening course of seventeen lectures suitable for, though not restricted to, candidates for the M.R.C.P. examination will begin on October 7th, and continue on Tuesdays and Fridays at 8.30 p.m., at the Medical Society's lecture room, Chandos Street, Cavendish Square. At the same place a course of evening demonstrations for the F.R.C.S. (final) will be given one day a week for six weeks at 8.30 p.m., including demonstrations in clinical surgery and pathology. Four demonstrators will attend each evening and will provide two cases each. The demonstrations will begin on Wednesday, October 8th. Particulars and syllabuses of all courses may be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

THE London School of Hygiene and Tropical Medicine announces a course of special psychological lectures by Dr. Millais Culpin, consultant to the Industrial Health Research Board, on Mondays and Wednesdays at 3 p.m. from September 29th to October 15th, inclusive. The subjects of the lectures are: importance of psychological aspects of illness; the history of medical views on psychology; nomenclature and classification; the incidence of psychological symptoms; the occupational neuroses; and theories of psychopathology. These lectures are free to members of the Public Health Service and others interested in public health work.

A POST-GRADUATE course on diseases of the nervous system will be held at the National Hospital, Queen Square, W.C.1, from October 6th to November 28th. It will consist of thirty-two clinical lectures and demonstrations at 3.30 p.m. each week-day except Wednesday and Saturday; instruction in the out-patient department at 2 p.m. on each week-day except Saturday; and eight pathological lectures and demonstrations on Mondays at 12 noon. The fee for the course will be £6 6s. A course of ten lectures on the anatomy and physiology of the nervous system will be arranged on Wednesdays and Fridays at noon if there are sufficient applicants; fee £2 2s. Twelve clinical demonstrations on methods of examination of the nervous system will be given on Tuesdays and Thursdays at 12 noon; fee £2 2s.

HEALTH WEEK in 1930 will be celebrated from October 5th to 11th, and up to the present 124 towns have undertaken to emphasize self-help in health as being the responsibility of the individual citizen. A leaflet giving particulars of the steps that may be taken to this end is obtainable from the secretary of the Royal Sanitary Institute, 90, Buckingham Palace Road, S.W.1. It deals with the formation of local committees, construction of a programme, suggestions for lectures, and the various sources from which assistance can be obtained.

A CONFERENCE of the National Smoke Abatement Society is being held this week-end in Leicester from September 26th to 28th. The subjects dealt with include atmospheric pollution as affecting visibility, and therefore aviation and fuel research and smoke abatement. Among the speakers are Dr. R. Veitch Clark, medical officer of health for Manchester, and Dr. C. Killick Millard, medical officer of health for Leicester, while the president of the conference is Dr. H. A. Des Voeux.

THE August issue of the *Journal of the Cancer Research Committee of the University of Sydney* contains an account of the first conference of cancer organizations in Australia, which was held at Canberra on March 20th and 21st. Reports were received from different parts of Australia, and resolutions with reference to the establishment and conducting of radium clinics were approved. Dr. E. H. Molesworth read a paper on the relative value of the various methods of treating cancer; this is published in full in the June number received.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal* should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are MUSEUM 9351, 9352, 9353 and 9354 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology, Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westcent, London.*

MEDICAL SECRETARY, *Medisecra, Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams *Bacillus, Dublin*, telephone 62550 Dublin); and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams *Associate, Edinburgh*, telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

NASAL CATARRH AND HARRISON'S SULCUS.

"H. A. T. G." asks for information regarding the title and date of appearance of an article on the subject of the prevalence of rhinitis in the newly born. It was stated that in the experience of the writer half the children born became infected with rhinitis within a very few days of birth. The author of this article also advanced the view that Harrison's sulcus in rachitic children was due to the effect of nasal obstruction tending to create a negative pressure in the thorax and thus to indirect moulding of the ribs over the liver. Our correspondent thinks the article in question appeared not more than six or seven years ago.

IDIOPATHIC HAEMORRHAGE IN THE NEWBORN

DR P O JOLLIE (Middlesbrough) writes The following brief description of a case may interest your correspondents on this subject On August 22nd I delivered a 9 para aged 45 of a fine baby girl who had a brisk haematemesis three hours after birth, this was repeated six times, at intervals of about twelve hours, associated with tarry motions two of which contained fresh blood The amount of blood lost, to use the words of one of your correspondents was truly amazing although I should hesitate to guess the amount Nevertheless at no time did the child seem the worse for the haemorrhage and the exertion of the vomiting except that it lost the raw ham colour peculiar to the newborn No treatment was adopted beyond complete rest for twelve hours and thereafter feeding with warm water flavoured with sugar The child has had no further haemorrhage since August 25th, and is going on normally

TECHNIQUE OF INJECTING VARICOSE VEINS

DR JOHN MCLAREN (Edinburgh) writes Most of the writers in the recent correspondence on the technique of injecting varicose veins urge the importance of taking great care that the injection actually enters the vein, since otherwise sloughing may follow One firm of chemists on the other hand, in their directions how to conduct this treatment give the advice that in certain circumstances injection round the vein is useful Will someone with experience supply a definite decision on this point?

INCOME TAX

Change in Employment

"M O H was, until November 1st 1929 acting as a whole time deputy and chief assistant county M O H and S M O at a salary of £850 per annum Since then he has held a part time post with permission to do other public work, but not general practice His total net earnings for the two years to April 5th 1931 will be £819 and £625 respectively, as compared with £802 net in previous years

*** In our opinion 'M O H' is clearly entitled to treat his employment as having ceased and been restarted as from November 1st, 1929, and therefore to have his earnings for 1929-30 and 1930-31 assessed on the amount of the actual year's earnings The matter is governed by Section 45 of the Finance Act, 1927, and the cessation or commencement relates to 'an office or employment' The inspector's contention that the nature of the employment" is unaltered is irrelevant, as there has undoubtedly been a change in the 'office If, on reconsideration the inspector is not prepared to give way, we suggest that M O H should write to the Secretary, Inland Revenue, Somerset House

Motor Car Expenses Private Use

A CORRESPONDENT has sent us a protest against a recent suggestion made in these columns that the only satisfactory basis of allocating car expenses is the mileage basis He encloses a statement setting out in detail various points on which such a basis would work unfairly against the practitioner, such as the greater ratio of time which professional use involves, the greater consumption of petrol, greater wear and tear on electric starter, brake parts gears etc and greater damage owing to weather We admit that our suggestion should, perhaps have been qualified, it would have been better to have said that the only *simple* basis of allocating car expenses is the mileage basis, but we were writing without reference to a practitioner who had such records of time, approximate number of gear changes, etc, as our present correspondent is apparently able to produce, and in the absence of such information it is difficult to get away from the mileage basis Perhaps we may add that some of the factors would not always work out as our correspondent suggests —for instance a practitioner who uses his car to take his family out for a Sunday might find the time factor against him if it included the hours when *the car was parked*, *private use often* involves as short trips as professional use and during holidays the car may travel over worse or more hilly roads than those where the practice is situated On the whole the mileage basis seems the best starting point, having regard to the importance of effecting agreement with the authorities if possible, but we agree that other factors may well be brought in—where their applicability can be proved—to modify the result of that allocation

LETTERS NOTES ETC

THE FOOT AND THE SHOE

"M B D P H" writes With reference to the letter from the general secretary of the Boot Trade Associations, Ltd, published in the *Journal* of August 2nd (p 200) may I make some suggestions as regards women's shoes My complaint is, first, that it is impossible to purchase a ready made shoe with anything approaching a straight inner line—that is, which will not in some measure deflect the big toe towards the middle line of the foot—and secondly, that one cannot buy a smart, dressy shoe for a wide foot I see no difficulty in the way of producing shoes of smart appearance, with low or with high heels, giving at the same time the very desirable straight inner line and sufficient width for the toes of wider feet Wide fitting shoes are invariably made heavy looking and with heavy ungraceful heels. Why not provide a neat wooden heel as in other styles? Lightness is essential to comfort That the pointed toe is not essential to smartness is shown by the fact that one of the most "dressy" styles of shoe at present on the market that with a high Spanish heel, has a wide round toe We may, I think, leave aside the question of the height of the heel as one which will be decided by *the demand of the wearer rather than by* the producer but improvement in the customary shape of the fore part of women's shoes the elimination of that shape which deflects the big toe is urgent, and at the same time I think, quite practicable The wide round toe is very neat, and is accepted by the dictates of fashion as compatible with a dressy effect With more attention to the ideal of the straight inner line, and perhaps also to the necessity for sufficient length in the round toed style, this shape should give all that can be desired in the matter of room for the toes and should be developed as far as possible for all styles of shoes The more or less pointed shoe which deflects the big toe and is a prolific cause of unsightly deformity should become a relic of the past I write from the difficult experience of procuring shoes for wide footed members of my own family who are not satisfied to wear "frumpy" shoes

PREGNANCY AND CERTIFICATION

"T G writes I am in complete agreement with "H R" (September 20th p 504) that some definite rule should be laid down with regard to certifying pregnancy I am also of the opinion that no housewife should be signed on while she carries on her household duties but only when she is confined to bed or obliged to employ a paid substitute, this last matter can be verified by the health visitors I have found in my practice that the patients have on several occasions been told by insurance agents that they can be "*signed on*" *if they can get a certificate* from the doctor, and, of course the good news soon spreads among a certain class of patients I have refused to sign on several patients and have had to suffer indirectly for my efforts to secure economy

NURSES' FUND FOR NURSES

THE committee of this fund, which was inaugurated by the *Nursing Times* in 1925 is in urgent need of financial support and other assistance in relieving the distress of poor elderly, and disabled nurses and midwives Some of these receive regular grants, chiefly to supplement their old age pensions while others with a bare subsistence, require help in sickness, especially during the winter months At present the list prepared by the committee comprises over 400 names and new applications are made every week The poverty of aged nurses—some of whom continued to work until they were well past 70—is indicated by the fact that those who have 20s a week are disqualified from receiving financial aid except for special reasons In its appeal the committee points out that if the nurses of all hospitals and institutions were to agree to deduct a penny from their monthly salaries the total amount would be sufficient to maintain its work It has been calculated that a gift of £100 will provide 5s a week for an old nurse for about eight years Another object of the committee is to raise funds for the endowment of homes for retired nurses So far accommodation has been found for twelve nurses at the Cow and Gate Home South Side Clapham Common where most of the occupants are over 70 years of age To enable this branch of its work to be carried on without anxiety, the committee estimates that an endowment fund of £2 500 is required Besides financial support help is requested in collecting subscriptions and in visiting and in writing to the lonely With the exception of some clerical assistance, the services involved in distributing the fund which include a thorough investigation into every case, are entirely voluntary Donations and gifts of clothing, parcels, papers, etc., should be addressed to the honorary secretary of the fund, *Nursing Times*, St Martin's Street, W C 2

ALLOTMENTS FOR THE UNEMPLOYED

DR E B HAZLETON (Sheffield) writes In order to counteract the evil consequences of unemployment—namely, wasted muscles, general want of tone and loss of self respect—a scheme for allowing *unemployed* men to work on allotments has been started in Sheffield with splendid results It has been found that when a steel worker or other manual labourer had been out of work for a year or two and then returned to work the wasted muscles were unequal to the task This is a very serious matter, but there is another aspect of the case not often thought of—that is such a man in a case of national emergency, would be useless for war purposes Allotment gardening gives the men a fresh interest in life and they become physically fit

MOTHERCRAFT

IN *Motherhood*, an attractive booklet, of which a third edition has appeared, Messrs Cow and Gate Limited combine sound advice on the hygiene of pregnancy and the care of the young infant with a pardonable advocacy of products of their own manufacture, and a not quite so pardonable attempt to undervalue products manufactured by others—for example vitamin D obtained by irradiating ergosterol Copies may be obtained (post free, 1s) from the Medical and Research Department, Cow and Gate House, Guildford

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 42 43, 44, 45 46 47 51, and 52 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 48 49, and 50

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page *151*

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

280 Incidence of Tuberculosis

P B NIELSEN (*Ugeskrift for Laeger* June 19th, 1930 p 603) recalls the work of Husted, who a couple of years ago conducted a series of Pirquet tests on probationers in a Danish hospital and who found that the frequency of positive reactions was approximately the same as for non tuberculous patients of the same age admitted to hospital—a positive reaction in about 65 per cent Nielsen's own studies cover the five year period January 1st, 1925 to January 1st 1930, his material consisting of the probationer nurses who joined the Communal Hospital in Copenhagen in this period They were selected lives in so far that they had to fill in a form indicating the existence of any tuberculosis in the nearest members of their families and present a medical certificate in which the existence of or predisposition to tuberculosis on the part of the applicant had to be specifically dealt with by the signatory to this certificate Altogether 341 probationers were appointed, the average duration of their service in hospital being 1 4 years During the five year period under review three cases of pleurisy with effusion, two cases of pulmonary tuberculosis and one case of renal tuberculosis were observed The number of patients suffering from pulmonary tuberculosis and treated in the Communal Hospital annually was about 140 Nielsen concludes that an incidence of 1 26 per cent of tuberculosis per year in these probationers does not differ appreciably from the incidence of this disease in young men of the same age, and he is inclined to be sceptical about the value of B C G vaccination of probationers on the lines laid down by Heimbeck and others in Norway

281 The Nature and Treatment of Sprue

P MANSON BAHR and H WILLOUGHBY (*Quart Journ Med*, July, 1930 p 411) give details from their observations of 200 cases of sprue They find that sprue is a disease *sui generis* attacking Europeans living in tropical and subtropical countries especially India It does not occur in Central Africa and it is rarely found among native races The etiology of sprue is not known but it is probably an infective condition, it has a definite incubation period, and is subject to periods of latency and recrudescence It appears as a specific inflammation ranging throughout the intestinal tract, associated with aphthous states of the mouth and tongue and destruction of the intestinal mucosa, it results in diminished power of absorption, with consequent starvation loss of weight, and severe anaemia The authors suggest that the virus may be ultra microscopic of low grade specificity It is acquired in the Tropics under certain definite conditions and from long contact with native races This virus may lie dormant in the human body for a number of years since the symptoms may only appear many years after the patient has left an endemic zone of the disease, cases are reported of twenty years' and eight years' delayed appearance of the symptoms Sprue is not a fatal disease the mortality in this series of 200 cases was only 3 (1 5 per cent) The treatment is chiefly dietetic aiming at the restoration of the power of absorption it is especially necessary to re establish a healthy blood picture This is readily attained in most cases by the transfusion of 400 to 500 c cm of blood, it is much helped by including liver in the diet which should also contain a liberal amount of fresh fruit There is no evidence that strawberries have any specific value Patients should avoid extremes of heat and cold, and occupations involving fatigue

282. Left Hypogastric Tenderness in Chronic Amoebic Dysentery

A DA SILVA MELLO (*Arch f Schiffs und Tropen Hygiene*, August, 1930 p 411), discussing the diagnosis of chronic amoebic dysentery, emphasizes the importance of left hypogastric tenderness, which he thinks is almost pathognomonic. Amoebiasis is a difficult disease to diagnose the history given by the patient is quite often misleading and employment of the rectal speculum is not always decisive, the examination of the stools may be negative in latent cases several times before a positive result is obtained and when several times before a positive result is obtained and when amoebae and cysts are seen the patient may prove to be only a carrier The author thinks that tenderness in the left iliac fossa along the descending colon and over the sigmoid flexure, almost always coexists with chronic amoebic dysentery, until that condition is cured It may, though rarely, indicate other conditions such as salpingitis or iliac vein thrombosis but far more often it is the sign of masked unrecognized amoebiasis Frequently he has found it the only clue to the cause of the patient's varied complaints which yatren, in sufficient doses abolished He reports the case of a man, aged 48 who had suffered for fifteen years from alternating diarrhoea and constipation and was losing weight on his necessarily much restricted diet He had left hypogastric tenderness but the stool examination was negative large doses of yatren cured him The author cites other cases, and adds that serious significance is always attached to tenderness at McBurney's point, in warm countries left hypogastric tenderness is just as important Tenderness in the right iliac fossa necessitates the exclusion of appendicitis, if there is tenderness in the left iliac fossa, amoebiasis must be definitely excluded or admitted

283 "Illness of Infection" in Measles

P R MYLES and R M GRENTHAL (*Arch of Ped*, June, 1930 p 399) record four cases in children aged from 7 months to 2 years which correspond to the condition described by Goodall in 1925 as the illness of infection in measles (see *Epitome*, March 28th, 1925 para 364), of which examples have since been described by Erlheim and Abercrombie (*ibid* April 27th 1929 para 352) In this condition, which is probably very rare a child a few hours after exposure to measles shows physical signs such as fever coryza conjunctival infection, and even a morbilliform rash, strongly suggestive of an attack of measles All the signs, however, disappear in a day or two but at the end of the incubation period undoubted measles develops The four cases reported by the present authors correspond with those previously described, but they admit that it is difficult to disprove Orel's contention that the so-called illness of infection in measles is due to a mixed bacterial invasion Non specific infection of the upper respiratory tract may cause the same symptoms, and further observations are required to determine whether the condition is an actual clinical entity or a non specific coincidence

Surgery.

284 Lateral Aberrant Thyroid Glands

L VAN DEN WILDENBERG (*Arch Internat de Laryngol, Otol Rhinol et Broncho Oesoph* May 1930 p 527) reviews the collected cases of laterally placed aberrant thyroids In this collection it was found that a single tumour was the rule but masses up to four in number in each side of the neck had been observed A case under the author's care is described in which there was a large colloidal goitre and five laterally placed aberrant masses the patient showed contraction of the pupil and narrowing of the palpebral fissure on the right side The masses were removed by operation and were found to be encapsulated they were of the same structure as the goitre but had no anatomical connexion with it Microscopical sections showed the presence of Hassall's corpuscles, thus demonstrating the developmental connexion between the thyroid and thymus glands Aberrant thyroid glands are more common in the female than in the male sex and are usually first noticed between the second and fourth decades They have a great tendency to undergo cystic degeneration and malignant changes have been observed in many cases These tumours are congenital and must not be confused with a similar but acquired condition where there is an anatomical connexion between the lateral masses and the thyroid gland itself their presence is always associated with goitre It is interesting to note that there are some cases of exophthalmic goitre where the thyroid gland is normal, but the characteristic changes of Graves's disease are found in the laterally placed masses The diagnosis is often difficult and the condition is frequently confused with cervical glands enlarged from any cause aberrant thyroid glands which have undergone malignant change are difficult to diagnose from secondary malignant glands with an obscure primary growth If there is any cyst formation aspiration and examination of the fluid may help the diagnosis and changes in the tumour associated with the menstrual function form a sign of great value if present The treatment is surgical and the author emphasizes two points in the operation The operator must be certain that a thyroid gland is present in the normal site The tissue removed must be at

once examined with all aseptic precautions, if parathyroid tissue is present it is immediately implanted into the muscles of the neck If, however, the lateral masses have undergone malignant change the mass is radically removed

285. Vessel Suture in Infected Areas

F SPATH (*Deut Zeit f Chir*, July, 1930, p 296), discussing the relative values of vessel suture and ligature, records a case showing that suture, if undertaken with the strictest asepsis, can succeed even in heavily infected regions A boy, aged 6, developed osteomyelitis of the lower end of the left femur with a large abscess cavity, which was opened and drained The temperature fell, but rose again four days after the operation A second examination revealed retention of pus in the popliteal space, and a haemorrhage from an opening 1 cm long at the junction of the femoral and popliteal arteries This opening was closed by four sutures, of which one broke loose owing to the fragility of the vessel wall The seam was covered with a piece of fascia lata, a strip of iodoform gauze was laid against it, and the whole was buried in healthy muscle Subsequent recovery was uncomplicated, one year later the peripheral pulses were equal and no circulatory disturbances had developed The only other course would have been ligature, which in large peripheral arteries is so often followed by gangrene Better results were given by suture than by ligature in the treatment of aneurysms, in both war and peace time A great deal depended on the efficiency of the collateral circulation Thrombo angiitis is rare after suture and supervenes later than after ligature The danger of delayed haemorrhage is no greater than after ligature in an infected area, and the healing of vessel injuries is very rapid, provided that the intima is intact Ligature of the corresponding vein, which has been successfully practised in conjunction with arterial ligature, is not recommended with arterial suture, since it may assist the spread of infection As regards technique, artery needles and the finest non paraffined silk were used Strict asepsis, the proper securing of the sutures, and the subsequent imbedding of the artery in healthy muscle tissue are important points The use of fascial strips for covering the seam is not recommended, as the case described the whole strip came away spontaneously from the wound on the eighth day

286 Surgical Treatment of Snake-bite

V POULSEN (*Ugeskrift for Laeger*, July 10th, 1930, p 681) recommends the following procedure which he adopted in June, 1929, in the case of a servant girl aged 21, bitten on the dorsum of the foot and through the stocking by a snake Two and a half hours later the foot was much swollen up to a point above the ankle, where a bandage had been tightly tied, and two punctures of the skin were found fully an inch apart The skin round these punctures, together with the underlying subcutaneous tissue, was anaesthetized by an injection of adrenaline and novocain The skin was incised in such a way that two flaps could be turned up in the centre of each of which the puncture wounds were situated, the flaps were squeezed between the fingers, and a large amount of serous fluid without a trace of blood, was removed The structure in the neighbourhood of the wound were massaged in its direction, and as much fluid as possible was removed The flaps were then replaced, and the wound was dressed No local or general signs of poisoning were observed after this procedure, but the wound took more than a month to heal, probably because of the poison it had contained

287 Metatarsal Injuries

IN a discussion of fractures of the metatarsal bones, A J BUKA (*Amer Journ of Surg*, July, 1930, p 135) recalls the main anatomical details concerned and reviews the mechanism of combined foot movements and progressions as related to the metatarsals These bones with their attachments are an intricate, closely related, and firmly compacted bony group, with muscles and many ligaments conferring support and movement They form collectively the whole of the transverse arch and part of the longitudinal arch, damage of these bones and their ligamentous or muscular attachments relaxes or destroys either or both of these arches, unless treatment is adequate Fracture of a metatarsal bone is caused either by direct or indirect violence, and the most susceptible and most frequent metatarsal to fracture is the fifth The fracture may be with or without displacement, and either simple or compound, the most serious sequel being infection A history of some foot injury is commonly given, the foot becomes very painful, and swelling with difficulty or inability to use it is present The pain is aggravated by motion, but in more severe cases the subjective symptoms are masked, especially if the patient is in a state of shock There is distinct tenderness at a point over the fracture, crepitus may or may not be present, and mobility of the fragments is not always noticeable X rays should always be employed for diagnosis The treatment involves immobilization of the foot in a plaster cast for no less than three weeks The foot is guardedly allowed to bear weight, this beginning at the end of the third week in simple, simple *fractures* and after the fourth week in complicated fractures, but only after immobilization in a cast for four weeks after completing the preliminary treatment of compound fractures When the cast is removed massage and movements with hot baths or bakings of the foot each day are instituted Crushed fractures, though often demanding amputation, may with patient treatment be thus preserved for subsequent reconstruction of the metatarsus

Therapeutics.

288 Treatment of Circulatory Failure in Diphtheria

F I SCHWENTKER and W W NOLL (*Bull Johns Hopkins Hosp*, June 1930, p 358) have previously shown that in diphtheria intoxication there is a profound disturbance of the carbohydrate metabolism, manifested in the early stages by increased glycogenolysis and carbohydrate utilization, so that in severe cases there is marked hypoglycaemia If the toxaemia is of longer duration, there is an increasing difficulty in the assimilation of dextrose from the blood stream, and progressive hyperglycaemia results Consideration of these facts suggested the following method of treatment Carbohydrate was supplied by intravenous injections of dextrose and then made available by the administration of insulin In cases of severe toxaemia and early circulatory failure in diphtheria the patient is given a large dose of antitoxin on admission to hospital Half an hour later, if no reaction has occurred, 10,000 to 20,000 more units of antitoxin and 20 grams of a 50 per cent solution of dextrose are injected intravenously, and 10 to 20 units of insulin intramuscularly Sedatives are administered if the patient is restless Intravenous injections of dextrose are repeated at intervals varying from 12 to 24 hours in each case accompanied by insulin After one or two injections the dextrose may be given in 10 per cent solution The administration of dextrose and insulin is repeated until recovery seems certain Of 14 toxic cases so treated 13 patients recovered.

289 A Possible Substitute for Morphine.

IN a preliminary note on the therapeutic administration of benzene sulphonate of oxydimorphine A LEULIER and B POMMI (*Bull de l'Acad de Méd*, July 22nd 1930, p 105) remark that although oxydimorphine is very different from morphine pharmacologically there is a close resemblance in chemical constitution Kolm Abrest states that it possesses none of the narcotic effects of morphine, but will produce clinical features characteristically absent in morphine addicts—namely, cough, vomiting, excessive intestinal peristalsis and flatulence, blood streaked diarrhoea, a rapid pulse, and vascular dilatation The salt is crystalline and forms a neutral solution in water (solubility 1 in 33), which can be sterilized at 100° C, and is painless on hypodermic injection A dose of 0 1 gram was administered to each of two guinea pigs, the one by the mouth and the other hypodermically, six hours later the slightly somnolent animals were killed, and the alkaloid, which had by then disappeared from the blood, was recovered from the liver A morphine addict, taking 0 05 gram per day, had 0.04 gram of this dose replaced by an equivalent amount of oxydimorphine In a month it was possible to keep him on 0 005 gram of oxydimorphine alone The patient had the same feeling of euphoria as with morphine, but complained of peripheral vaso dilatation and, during the first two or three days, had two or three motions daily instead of his usual one A patient with severe Pott's disease of the cervical vertebrae, causing root pains in the upper limbs, obtained relief from pain for several hours with the injection of 1 c cm of a 1 per cent solution of this drug The authors conclude from these early experiments that oxydimorphine possesses the anaesthetic and euphoric qualities of morphine, at any rate when administered in small doses The euphoric action, indeed, raises the question whether, owing to the risk of a habit being formed, restrictions should not be placed on its sale

290 The Employment of Vaccines and Serums

POINTING out the inestimable value of both vaccines and serums D G CAMPBELL (*Canadian Med Assoc Journ*, July, 1930, p 10) deprecates their indiscriminate and ill judged use Under normal conditions, protection against infection depends upon the hypersensitiveness of the subject to the bacterial protein, and a vaccine may change this hypersensitiveness in one of the following ways It may increase it, or it may desensitize the individual, repeated

injections may result in developing both immunity and hypersensitiveness, in chronic infections it may depress the already partly established immunity, or it may even abolish all cellular and vascular reactions Hence a vaccine is not a simple harmless therapeutic agent The use of vaccines for active treatment lacks a scientific basis but they have a very definite field in preventive medicine particularly in the typhoid group and in cholera Vaccine therapy is a specific therapy in which a correct bacterial diagnosis should be made, and treatment instituted accordingly The value of prophylactic inoculation must be determined by three factors the risk of infection and the consequences if infection occurs, the risk or disability attaching to the treatment, the efficiency and duration of the immunity set up Vaccines are intended for hypodermic injection the results of their oral administration have so far not been convincing No generalization as to whether a stock or autogenous vaccine is to be preferred, nor as to dosage and frequency is practicable, except that it is wiser to give vaccines at long rather than at short intervals In spite of many disadvantages serum therapy has proved the most efficient measure against infections Serum may be administered by five different methods subcutaneously intramuscularly intravenously intraperitoneally and intrathecally Each has advantages and definite indications for its use All serum therapy is more efficient the earlier in the disease it is used, though in some infections its efficacy is lost more rapidly than in others Campbell comments briefly on the serum treatment of diphtheria scarlet fever erysipelas meningitis tetanus poliomyelitis, and measles A few diseases of less interest yield satisfactorily to serum therapy, such as botulism snake bite and bacillary dysentery He believes that in estimating the value of any particular serum the results should closely approximate those obtained in diphtheria which may be considered as a standard and that any serum which must be given several times over a week or more before producing results is a much more doubtful therapeutic agent

Neurology and Psychology.

291 Disorders of Handwriting Associated with Adenoid Enlargement

D J VASILIU (*Arch Internat de Laryngol, Otol Rhinol et Broncho-Oesoph* May, 1930 p 522) reviews the history of the study of handwriting disorders and explains how they may be produced by lesions on the motor or sensory side of the central nervous system, or as a failure of association These disorders are therefore seen in many organic nervous diseases and also in hysterical and hypnotic states but Vasiliu has been particularly interested in those cases which have been found to have some relation to the adenoid state The handwriting of the adenoid child is irregular, the letters are unequal in size and letters and syllables may be omitted the lines wander from the straight The author has observed a large number of school children and all who have shown these abnormalities have been greatly improved by operation The condition is believed to be due to some abnormality in the action of the sympathetic and parasympathetic systems It is claimed that it is well established that a hormone is produced by the adenoid tissue and that the classical symptoms of hypertrophied adenoids are due to an excess of this hormone in the circulation The handwriting disorders may be explained as being attributable either to the deleterious action of an excess of this hormone on the cerebrum, or as due to an anaemia of the brain which is produced by a vaso-constriction, which in its turn is due to overaction of the sympathetic system resulting from an excess of the adenoid hormone

292. Polyneuritis of Dietetic Origin

I S WECHSLER (*Med Journ and Record* May 7th 1930 p 441) has for many years observed cases of polyneuritis without being able to determine their etiology laboratory examinations failed to reveal specifically either a causative or contributing factor In nearly all of the cases there was a history of vomiting or gastro-intestinal disturbance or restriction in diet The question then arose whether these were not cases of food deficiency possibly avitaminoses which were the result of direct privation or of poor digestion and absorption of food Eight cases are reported in each of which there was a history of vomiting or starvation or diet restriction to warrant the assumption of food deficiency Their importance according to the author lies in the recognition of a deficiency factor in cases of polyneuritis in which the etiology was obscure and in the fact that the deficiency may be due alike to privation from within the body as well as without It is not merely a question of lack of food rich in vitamins, but of an inability, owing to vomiting or other cause, relating to digestion and absorption or assimilation The view is beginning to be entertained seriously that food deficiency is at the basis of some of the degenerative diseases of the nervous system Sufficient evidence has been adduced to show that what has previously been regarded as a peripheral nerve inflammation is in reality due to spinal cord involvement This is particularly true of the polyneuritis caused by lead and that occurring in diabetes These dietetic forms of neuritis may be due to food privation, the result of defective or perverted metabolism The same pathological basis may be applicable to alcoholic polyneuritis and it is possible, therefore, that what passes for an inflammatory type of neuritis is not really a primary inflammation but a deficiency neuritis because the patients do not eat or do not absorb their food It is quite possible that, in the neuritis occurring in prolonged exhaustion and cachetic states, actual starvation, which in certain cases results in avitaminosis is the cause of the polyneuritis and not cancer, tuberculosis or other chronic disease

293. Lymphosarcoma Involving the Central Nervous System

THOUGH occasionally the structures about the central nervous system such as the bones of the skull or vertebrae, may show the presence of lymphosarcomatous nodules the brain and spinal cord are rarely the seat of direct invasion by these neoplasms and but few such cases have been recorded C DAVISO and J J MICHAELS (*Arch Int Med* June 1930 p 908) report seven cases presenting neurological signs which occurred in 26 cases of lymphosarcoma admitted to the Mount Sinai Hospital Detroit since 1922. Four of these were verified by post mortem examinations three showed signs of compression of the cord (only one case has been recorded previously) and the remaining one presented involvement of the brain Two of the seven cases showed invasion of the cranial cavity localized chiefly in the middle and posterior fossae four showed involvement of the vertebral column or the spinal meninges, which caused compression of the cord or the posterior roots, resulting in herpes zoster in one case and one case showed involvement of the facial nerve peripherally Of the cases in which the cranial cavity was invaded the cervical lymph nodes were involved early in three, in the remaining case the involvement of the cervical glands did not occur till late in the disease One case with early cervical glandular involvement did not show any evidence of invasion of the brain tissue by the lymphosarcoma as is usually seen in metastasis from other tumours, especially carcinomata the invasion in this case occurred through the lymphatics As the brain proper is not supplied by lymphatics, this readily explains the absence of cerebral invasion by lymphosarcomata or Hodgkin's disease In the cases showing involvement of the cord in the form of compression enlarged cervical lymph glands did not become evident until late in the disease In none of these cases was the spinal cord directly involved All except one of the seven patients responded well at first to treatment by deep x rays and radium there being recession of the lymphosarcomatous masses with early improvement in the symptoms After a few applications the enlargements and symptoms recurred however and finally failed to respond this is characteristic of all lymphosarcomata None the less, the authors conclude that this form of treatment though only palliative, is to be recommended at present

Obstetrics and Gynaecology

294 Primary Ectopic Chorion Epithelioma of the Vagina.

ACCORDING to G HALTER (*Zent f Gynäk* May 24th 1930 p 1282) primary ectopic chorion epithelioma of the vagina —namely the appearance of a chorion epithelioma in the vagina at a time when an intrauterine pregnancy is present— is rare the distinction in diagnosis from metastatic vaginal tumour can only be made when a systematic examination of the uterine contents is possible The tumour results from the retrograde passage of chorion elements through the dilated pelvic veins Primary ectopic chorion epithelioma of the vagina in combination with normal intrauterine pregnancy has only been recorded in one case—that reported by Walthard Distinction is necessary of these cases from those of hydatidiform mole metastases in the vagina which develop as vesicular masses 'organotypically', in contrast with the histiotypical structure of chorion epithelioma. Primary ectopic chorion epithelioma of the vagina in combination with intrauterine hydatidiform mole has been recorded by Schickele Sunde and others and Halter adds a personal case in which a two para, aged 43 was admitted to hospital after insertion of a vaginal tampon for haemorrhage from an ulcerated chorion-epitheliomatous nodule on the

posterior vaginal wall The size of the uterus corresponded with the two and a half months' amenorrhoea which was reported, albuminuria was absent Total hysterectomy was performed, but the patient died on the eighth day from pulmonary infarction No lung tumour was found, the uterus contained a hydatidiform mole, but no sign (even after examination of serial sections of the site of insertion) of chorion epithelioma No chorionic villi had crossed the decidual muscular boundary As regards the treatment of primary ectopic chorion epithelioma, Halter differs from those who before removing the uterus would examine its contents The organism, he points out, has already shown its inability to resist the development of displaced chorionic fragments, and whether the uterus contains a chorion epithelioma, a hydatidiform mole, or a normal ovum, speedy removal (by hysterectomy) of the source of the chorioidal tissue is indicated

295 Extraperitoneal Caesarean Section

K B STELLE (*Amer Journ of Obstet and Gynecol*, June, 1930, p 747) states that although clinical evidence is accumulating of the value of cervical Caesarean section, an appreciable number of cases occur in a large maternity service which call for suprapubic delivery in circumstances in which surgical entry of the peritoneal cavity would be extremely dangerous In these cases distinct advantage is offered by extraperitoneal section, and a record is given of 59 such operations in which the Latzko technique was employed The average age of the patients, half of whom were primiparae, was 28, 8 had normal pelves, 28 had flat, 9 had generally contracted ones, and in 10 the pelvis was of the "male" type The number of maternal deaths was 5 (8 5 per cent), in spite of the apparently unfavourable pre operative circumstances that (1) twelve patients had undergone some previous attempt at operative vaginal delivery, (2) the average duration of labour before operation and the average time since rupture of the membrane were respectively 28 5 and 21 5 hours, and (3) an average of five vaginal examinations had been made, and two thirds of the patients showed some degree of exhaustion before operation Only four presentations were by the breech, and in only five of the vertex cases was the head partially or completely engaged From two fingers' to full dilatation of the cervix was present in five out of six patients Post operative complications were remarkably infrequent, but there were four cases of vesico abdominal, vesico vaginal, and/or vesico uterine fistulae Stillbirths and neo natal deaths together numbered only six The general conclusion is drawn that extraperitoneal Caesarean section causes a minimal risk of peritonitis in infected cases In addition to possessing all the advantages of a low double flap operation it is extra peritoneal and permits drainage

296 H T BURNS (ibid, p 759) describes fully the technique of the Latzko extraperitoneal Caesarean operation, he records nine cases with one accidental opening of the peritoneum and only one post-operative catheterization He finds the chief indications in (1) infected cases in which delivery by the vagina or by intraperitoneal Caesarean section appears to be risky for mother and infant, (2) cervical dystocia with prolonged labour, (3) cases of "borderline" pelvic dimensions in which a trial labour with forceps application has been given, and (4) very prolonged and unsuccessful trial labours Among the good features of the operation, apart from the preservation of an intact peritoneum, are the relatively slight traumatism, and therefore slight shock If the Latzko pro cedure is kept in view in cases of slight or moderate pelvic contraction the incidence of Caesarean sections is lowered, because a trial labour can be granted with impunity

297 Like other recent German writers L NÜRNBERGER (*Archiv für Gynäkologie*, July 2nd, 1930, p 106) believes that extraperitoneal Caesarean section, although latterly fallen into disrepute, has still a sphere of usefulness, especially in certainly or presumably infected cases Concerning the chief disadvantage at the operation—its technical difficulty—he points out that this diminishes with increasing practice, he is able to report a series of sixty extraperitoneal Caesarean sections performed during the past two years, with a duration of thirteen to thirty five minutes and a usual interval between skin incision and delivery of five to fifteen minutes Accidental opening of the peritoneum is sometimes unavoidable, it is of less grave import when it happens before the uterus has been incised than during the extraction of the infant It occurred in these circumstances in eight and five cases respectively of the present series The sixty cases, of which ten were febrile before operation were without maternal mortality from peri tonitis there were only three deaths—two in eclamptics and one from late post partum haemorrhage followed by hyster ectomy and pneumonia The importance is stressed of invariably inserting a gauze drain in the connective tissue, as advised by Küstner

Pathology.

298 The Diagnosis of Plague in Rats

KISTER (*Zentralbl f Bakt*, July 28th, 1930, p 433) records statistics for the last thirty years of the examination of rats and mice from suspected plague infected ships at Hamburg Of 6,466 ships examined, 64 (1 per cent) proved to be infected, of 98,830 animals examined, 669 (0 68 per cent) were infected The number of positive results has diminished greatly of recent years, possibly on account of more adequate pre ventive measures at the ports of origin The number and percentage of infected rats on any one ship were subject to great variation, sometimes only a single animal was found infected, sometimes nearly every rat on the boat was suffer ing from plague The cadavers were examined for fleas 93 8 per cent of the rat fleas were identified as *Xenopsylla cheopis*, in the Hamburg sewers, however, only *Ceratophyllus fasciatus* was found In the earlier years 97 2 per cent of the rats were *Rattus rattus*, but in recent years this proportion has diminished In 1929, for example, of 7,565 rats examined, 69 2 per cent were *R rattus*, 18 5 per cent *R alexandrinus*, and 12 3 per cent *R norvegicus* The author lays great stress on the polar stained barrel forms seen in fresh material examined microscopically, and on the characteristic rings and discs in putrefying material Organisms of the haemorrhagic septicaemia group and *Past pseudotuberculosis* were never encountered For cultural purposes Kister uses gelatin, agar, and Endo plates On agar two colony forms may be met with (1) a rather flat, delicate, greyish white colony with an irregularly crenated edge, and (2) a larger, yellowish, granular more juicy colony, with an effuse peripheral extension On Endo's medium the same two types of colony are found, but they are at first pale, and later reddish in colour For inoculation, rats, mice, and guinea pigs are used In putrefying animals the virulence of the plague bacilli may be lowered, and large quantities of material must be inoculated, and further culture passage performed The definitive diagnosis should rest on pure cultures being obtained, agglutination, and animal inoculation

299 Fixation of Calcium in the Tissues

A SAVICKI (*Paris Méd*, July 26th, 1930, p 89) discusses calcium fixation in physiological processes such as the growth of the skeleton, the union of fractures, the isolation of areas of microbic infection, and the maintenance of acid base equili brium, which permit continuity of life or promote resistance to disease The author discusses the ways in which this function of the body can be aided during pregnancy, infancy, adolescence, and in tuberculosis In all these cases he recommends the administration of suitable foodstuffs—milk and fruit juices for infants, and for the other groups milk, fresh fruit, green vegetables, eggs, cheese, wholemeal bread, and vegetable oils Vitamin D is of the greatest importance in the fixing of calcium in the tissues, and it is very readily administered in irradiated ergosterol, the author considers that the discovery of this preparation has been of great service to calcium therapy For rachitic infants he advocates 0 25 mg daily, increasing to 5 to 6 mg

300 A Method of Demonstrating the Incompatibility of Blood for Transfusion

IN order to avoid the ill effects due to transfusion of unsuit able blood L YMAZ (*Rev Med de Barcelona*, June, 1930, p 546) has devised a procedure which has given good results in his hands The theoretical basis of the method is the effect produced in the plasma of the recipient by a small intravenous injection of incompatible blood, the symptoms being those of a transient vago sympathetic disturbance, demonstrable in the peripheral circulation by leucopenia, modification of the differential leucocyte count, and a slight fall in the diastolic arterial pressure The method is simple A white cell count and a percentage differential leucocyte count are made of the recipient's blood, and the arterial pressure is determined with Pachon's oscillometer, 2 or 3 c cm of the citrated blood of the donor (1 drop of a 25 per cent citrate solution per c cm of blood) are injected into a vein at the bend of the elbow, and three minutes later the above investigations are repeated If the peripheral blood shows a leucopenia and a disturbance in the differential count the blood of the donor is indicated as unsuitable The modifica tions in the arterial pressure are said to be less reliable than the white cell counts This experimental shock effect has been brought about with blood samples of Group IV (universal donors), Group I (universal recipients), and also between donors and recipients of the same group Ymaz claims that the method demonstrates blood incompatibilities without provoking any severe symptoms, it is also simple and safe The proportion of incompatibilities observed was similar to that obtained by other workers using other methods

What about taste?

MANY patients still believe innocently that the medicine must be bitter to be efficacious

Agarol Brand Compound the original mineral oil and agar agar emulsion with phenolphthalein, is for that up to date generation that wants its medicines in the proverbial "sugar coating"

No excuses are needed for its taste any more than for its effectiveness Agarol Brand Compound is exceptionally palatable without artificial flavouring It *flows freely* from the bottle, and can be mixed with any liquid or soft food.

Just enough mineral oil to carry unabsorbable moisture to the intestinal contents, keep them soft, and so make evacuation easy and painless By *gentle stimulation* of peristalsis, Agarol Brand Compound makes the result certain, and aids in re-establishing regular habits

One tablespoonful at bedtime —is the adult dose

Final decision on the true worth of Agarol Brand Compound rests with the physician We will gladly send a liberal quantity with literature, for trial.

AGAROL BRAND COMPOUND *for Constipation*

FRANCIS NEWBERY & SONS, LTD, 31-33, Banner Street, London, E C 1.

Prepared by WILLIAM R. WARNER & CO., INC., *Manufacturing Pharmacists Since 1856*

Wolsey is light but warm

Health questions of all sorts come to you for answering

Mothers, especially perhaps, ask your advice about children's diet and dress The advantages of wool are that it is absorbent and keeps the temperature even Wool is light but warm

If one undergarment is woollen, that is a safeguard, and fewer others need be worn

Besides, the texture of modern woollen underwear, for children and adults alike, is soft and airy and pleasant to the touch

For thirty years Wolsey has protected people's health Better value than Wolsey cannot be bought

It's the Tobacco that Counts

NCC 915

Issued by The Imperial Tobacco Company (of Great Britain and Ireland), Limited

ONLY BREAKAGE CAN DESTROY ITS HEALTH VALUE

Only by breakage can you destroy the value of "Vita" Glass as a permanent inlet for the ultra-violet rays

One of the most interesting tests ever made in proof of this permanency is being carried out by the Building Research Station, and an interim report states —"The behaviour of 'Vita' Glass in sunshine cannot be deduced from artificial solarisation without serious risk of error" "Vita" Glass exposed to artificial radiation regains its solarised level of transmission on subsequent exposure to natural daylight, after which continued exposure to sunlight causes no further change.

Those interested in "Vita" Glass for their own use or for use in buildings under their control are invited to write for full particulars to the "Vita" Glass Marketing Board, 9 Crown Glass Works, St Helens, Lancashire.

"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers and Builders.

"VITA" GLASS

"Vita" is the registered Trade Mark of Pilkington Brothers Limited, St. Helens

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

1 It is individually fitted to suit the case for young middle aged, or old
2 It is simple and true to tone, and leaves the hands free
3. It removes strain thus relieving head noises, giving inconspicuous hearing
4 It conveys sounds from varying ranges and angles
5 It is entirely different unconspicuous, and carries a guarantee and service system
6. It is suitable for "hard of hearing" or acutely deaf through various causes
7 It is helpful for conversation, music talkies wireless, home, office, public work, and sports

FREE HOME TESTS
arranged for Doctors and Patients
Medical Prescriptions made up to the minutest detail

"ARDENTE" STETHOSCOPE
Mr R H Dent makes a Stethoscope specially for members of the medical profession suffering from deafness Many are in use, and excellent results are reported on the latest as evidenced by the interest shown at the last B M A Meeting

KEEPING EXPENSES DOWN AND APPEARANCES UP

£1 MONTHLY DOES IT

Unquestionably one of life's greatest problems is keeping expenses down and appearances up, especially as most people take us at our face value

Keith Bradbury's object is to help you keep appearances up and expenses down, by offering to provide you with West-End clothing on terms from £1 per month to suit your convenience. (Cash or quarterly accounts available if preferred)

All garments are cut and fashioned to satisfy the exacting needs of men accustomed to the master touch of the West-End tailor, and every customer is waited upon by one of the Principals

A FREE VALET SERVICE is also provided to preserve the smart appearance of garments after purchase, so you see we take a sincere interest in our customers' good appearance

An interesting catalogue, patterns or particulars of our special financial arrangements will be gladly sent on request, or better still, may we have the pleasure of a call

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY

President THE MOST HON THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders (persons suffering from incipient nervous and mental disorders as well as certified patients of both sexes are received for treatment. Careful clinical biochemical bacteriological and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital in detached grounds, with a separate entrance to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Hombleres treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

Ministry of Health

APPOINTMENT OF DEPUTY REGIONAL MEDICAL OFFICERS

The Minister of Health invites applications from registered Medical Practitioners for appointment as Deputy Regional Medical Officer on the staff of the Ministry in various parts of England and Wales for the discharge of combined clinical and administrative duties in connection with the National Health Insurance Medical Service.

The rate of remuneration will be £800 per annum rising by annual increments of £30 to a maximum of £1 100. No cost of living bonus is payable in addition thereto.

Successful candidates under the age of 50 years will be appointed to this scale and will be established Civil Servants with the usual pension rights. Those who are considered to possess exceptional or special qualifications may be allowed to enter the above scale at a commencing salary of £850 per annum.

Successful candidates of the age of 50 years and upwards (at the time of appointment) will be remunerated on the above scale and will receive unestablished non-pensionable appointments. In special circumstances where a candidate in this category has special qualifications and experience the commencing salary may be advanced to a point in the scale not exceeding £1 000 per annum inclusive.

Above the grade of Deputy Regional Medical Officer there are at present 35 posts of Regional Medical Officer (32 in England and 3 in Wales) rising to a maximum of £1 400 per annum inclusive and 4 posts of Divisional Medical Officer rising to a maximum of £1 600 a year inclusive. The above numbers are however subject to revision from time to time as the exigencies of the Service may determine. When vacancies are to be filled among the Regional Medical Officers preference will be given to those who have served as Deputy Regional Medical Officers.

Candidates must be Medical Practitioners of not less than ten years standing and not exceeding the age of 55 years with a wide experience of general practice especially amongst the industrial population; preference will be given to candidates who served in His Majesty's Forces during the war.

Deputy Regional Medical Officers are required to devote their whole time to the Public Service and to perform such duties as may be assigned to them by the Minister from time to time. These include acting as Deputy to the Regional Medical Officer in the work carried out by the latter

(a) as Medical Referee in cases of insured persons referred for a second medical opinion on questions of incapacity for work or of restoration of working capacity;

(b) in assisting in the administration of the Insurance Medical Service.

Deputy Regional Medical Officers must be prepared to reside in the area from time to time assigned to them.

Canvassing. Members of Parliament or Officers of the Ministry will render a candidate liable to disqualification.

Forms of application with further particulars of the appointment may be obtained from the Director of Establishments, Ministry of Health, Whitehall, S.W. or for Wales, The Welsh Board of Health, City Hall, Cardiff.

No application can be considered unless received on the prescribed form not later than October 27th, 1930.

Eastbourne Princess Alice Memorial Hospital (96 Beds)

Applications are invited for the post of HOUSE SURGEON (male). Salary at the rate of £150 per annum with board, lodging and laundry. The appointment is for six months. Duty is to commence immediately. Candidates must be unmarried, fully qualified and registered. Applications stating age, qualifications etc., accompanied by copies of not more than three recent testimonials (one of which must be from Medical School) should be sent to the Secretary.

Victoria Hospital, Burnley (120 Beds)

Applications are invited for the post of HOUSE PHYSICIAN (male). The appointment is for six months in the first instance and carries a salary of £150 per annum with board, etc.

The Hospital is approved by the London University for the purposes of the M.B. and B.S. examinations.

Applications with testimonials should be delivered to the undersigned forthwith.

C. D. W. COOLING,
Secretary Supt.

Sept. 23rd, 1930.

Rowley Regis Urban District Council

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER (Temporary, Half-time).

Applications are invited for the above post, the duration of which will not exceed one year. The salary will be at the rate of £300 per annum with travelling expenses within the Urban District. The duties will be carried out under the supervision of the Council's Medical Officer of Health (who is also School Medical Officer) and in his absence of the Deputy Medical Officer. Candidates should have had three years' experience since qualification and special experience in diseases of children will be a recommendation. The appointment will be subject to approval by the Ministry of Health and Board of Education. The candidate will be required every afternoon, except Saturday, from 2 to 5, and one morning in alternate weeks.

Applications, with particulars of qualifications, to be addressed to The Clerk Council House, Old Hill, Staffordshire, not later than October 2nd.

County Borough of Barnsley

SENIOR DENTAL SURGEON

Applications are invited from Licentiates in Dental Surgery for the position of a Whole-time Dental Surgeon to the above Authority at a commencing salary of £600 per annum.

September 24th, 1930. By Order of the Council. ALFRED COX, Medical Secretary.

West London Hospital,
Hammersmith, W.6. (234 Beds.)

Applications are invited for the post of HONORARY OPHTHALMIC SURGEON, for which the present Honorary Assistant Ophthalmic Surgeon is a candidate. In the event of his election there will be a vacancy for an Honorary Assistant Ophthalmic Surgeon, for which applications are also invited.

Candidates must be Fellows of one of the Royal Colleges of Surgeons of England, Edinburgh or Ireland. The successful candidate will be required, in addition to his other duties, to undertake such teaching for the Post-Graduate College as the Board may approve.

Application, with copies only of testimonials, must reach me not later than Thursday, October 23rd. Candidates must attend the Meeting of the Medical Council on Friday, October 24th, at 4.30 p.m. and prior to that date call upon and send copies of application and testimonials to each member thereof. They must not canvass members of the Board of Management, but nevertheless must send copies of their application and testimonials to each member thereof; and if so notified, be in attendance at a Meeting of the Board at 5 p.m. on Tuesday, October 28th, when the election will be made.

H. V. HADGE, Secretary.

Western Ophthalmic Hospital,
Marlebone Road, London, N.W.1.

SENIOR HOUSE SURGEON (Resident) required November 1st.

JUNIOR HOUSE SURGEON (Non-resident) required November 1st.

Applications are invited for the above posts. The salaries are at the rate of £150 and £100 per annum respectively, and the appointments are for six months. Previous Ophthalmic Experience is required. Application, accompanied by copies of three testimonials, should reach me by first post on October 1st.

Candidates should be prepared to attend before the Medical Committee on Friday, October 3rd, at 5 p.m.

Applicants for the Senior post should state if they are prepared to accept the Junior one.

H. W. BURLEIGH,
Honorary Secretary.

Mater Misericordiae Hospital,
DUBLIN.

(Founded 1852 and conducted by the Sisters of Mercy.)

The following positions are now vacant:

VISITING SURGEON.

Applications, stating qualifications and academic distinctions, accompanied by three duplicate copies and by three duplicate copies of not more than three recent testimonials must reach the Secretary of the Medical Board on or before October 4th. The Medical Board will arrange in order of merit the names of those candidates who they deem suitable and whose appointment they could advise, and will submit the list to the authorities of the Hospital with whom the final act of appointment rests.

TWO ASSISTANT SURGEONS.

Applications are also invited for the position of Two Assistant Surgeons on or before October 4th. Each candidate is required to forward at the same time three duplicate copies of his application and also three duplicate copies of no more than three recent testimonials. The Medical Board will arrange in order of merit the names of the candidates whom they deem suitable and whose appointment they could advise, and will submit the list to the authorities of the hospital with whom the final act of appointment rests. The successful candidates will hold office for three years at the expiration of which term they will be eligible for re-election.

Canvassing for any of the above positions will render a candidate liable to disqualification. Candidates who desire further information are required to communicate with the Secretary of the Medical Board.

The Hospital for Epilepsy and Paralysis,
Maida Vale, W.9.

DENTAL SURGEON REQUIRED.

Applications are invited for the post of Honorary Dental Surgeon. Application, with copies of not more than three recent testimonials, should reach me by October 4th.

H. W. BURLEIGH,
Secretary & Gen. Supt.

The Hospital for Sick Children,
Great Ormond Street, London, W.C.1.

A HOUSE SURGEON and a HOUSE PHYSICIAN are required on October 14th.

Gentlemen are invited to send in their applications, addressed to the Secretary, before 12 o'clock on Monday, October 6th, with copies of not more than three testimonials given specially for the purpose and also evidence of their having held a responsible hospital appointment.

The appointments are made for six months. Salaries at the rate of £100 per annum, laundry allowance £5, board and residence in the Hospital.

Candidates must be unmarried and possess a medical qualification to practise.

A candidate must be in attendance to appear before the Joint Committee, if required, at their Meeting on Wednesday, October 8th, at 4.45 p.m. precisely.

Forms of application and copies of the rules may be obtained from the Secretary.

By Order of the Board of Management,
JAMES McKAY,
September 1930. Secretary.

Durham County and Sunderland EYE INFIRMARY

Wanted TWO OPHTHALMIC SURGEONS for the above Institution to attend during the forenoon on three alternate days per week and one afternoon clinic per week. Commencing salary £350 per annum. Applications, with copies of recent testimonials, to be sent to JOHN BUTTERFIELD, Secretary, Eye Infirmary, Stockton Road, Sunderland.

Western General Dispensary,
Marylebone Road, London, N.W.1.

There is a vacancy in the post of HONORARY OPHTHALMIC SURGEON to the Dispensary. Applications must be sent to the Secretary of the Royal College of Surgeons, England, to whom all testimonials must be sent, and should reach him on or before Thursday, October 2nd.

(Appointments continued on p. 50.)

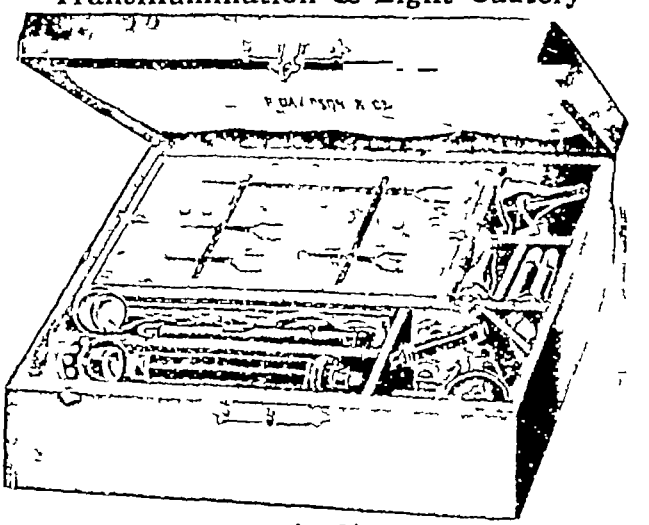
Davidson's Productions for the Medical Profession

"PARAGON" ILLUMINATED TYPES



Can be hung on wall, or stood on a shelf or table

By means of an ingenious arrangement of the light and mirrors the most brilliant illumination possible is obtained with a lamp of a low candle power A metal chimney, asbestos lined with ground glass shade (for light) and shutter (for reducing the size of illumination) is supplied for Ophthalmoscopic or Laryngoscopic examinations (Size 18in × 18in × 4in)

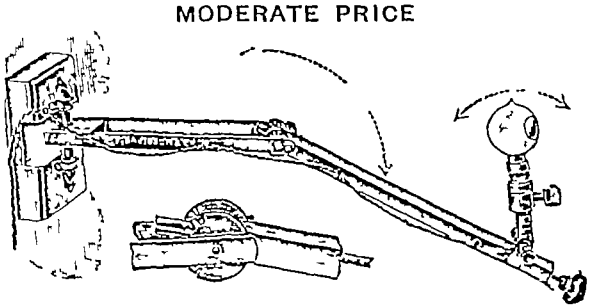
Price complete (without bulb) or with Incandescent Gas Burner £3 10 0 Two Sets of Snellen's Types instead of "Complete" Sight Test Card if desired

"Davon" Outfit for Eye, Ear, Nose, and Throat Examination, Transillumination & Light Cautery

No 54

Lighting Tube with 2 Mirrors 3 Aural and 1 Nasal Speculae Twin Lamp Fittings for Transillumination of the Antrum and Sinuses Single Fitting for the Sclera, Electric Ophthalmoscope and Rotinoscope Cautery Handle Cords, and 4 Burners 2 Davon Dry Batteries and Plug enabling either or both to be used, 3 Metallic Filament Lamps Connecting Cords etc

In Walnut box with handle £11 15 0



Other Ear, Nose, and Throat outfits from £3 12 6

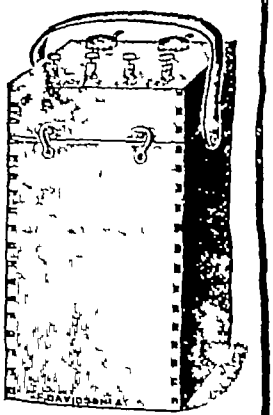
Our Davon Battery has been before the profession for over 20 years and maintains its reputation Many Doctors have used one for 2 years and more *INSIST UPON HAVING THE DAVON* (our registered trade mark)

OCULIST'S TRIAL CASES, all Lenses Mounted, Complete with Adjustable Trial Frame, "Complete" Sight Test Card, etc. - from £10 10 0

THE "DAVON" BRACKET

Well made and serviceable at a very MODERATE PRICE

By a slight pressure upon the ebonite knob (seen below the lamp) a clutch is caused to disengage from one of a series of teeth in the discs visible at the hinge, by releasing the pressure the clutch is self locking in the position the lamp is desired to assume One hand only is necessary to adjust, and when not in use the lamp will fold flat to the wall

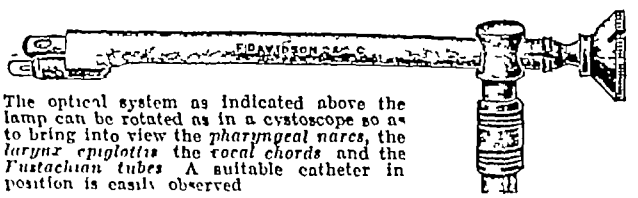


Price without bulb £2 2 0

Target frosted bulbs (please state voltage), each 3/6

"DAVON" PORTABLE SET FOR CAUTERY & LIGHT.

No 18C 0 to 4 Volts
Actual capacity 20 ampere hours



This constitutes an achievement in the production of a highly efficient apparatus at a moderate cost

No 18C comprises a new pattern 4 volt glass accumulator made without plate separators and concealed rheostats for cautery and light actuated by rotating knobs on the lid These permit of very easy and gradual adjustment Separate terminals for cautery and light allow of both being employed at the same time

Walnut Box with strap handle
Price £4 4 0

Cautery Handle, Cords and 2 Burners £2 4 6

The optical system as indicated above the lamp can be rotated as in a cystoscope so as to bring into view the *pharyngeal nares*, the *larynx epiglottis* the *vocal chords* and the *Eustachian tubes* A suitable catheter in position is easily observed

ELECTRIC PHARYNGOSCOPE.

(FOREIGN)

(New optical system giving much improved view)

Price in Walnut Box £6 5 0

With "Davon" Battery and Rheostat, contained in Walnut Box £7 5 6

MEDULLA RUBRA

BONE-MARROW IN ANAEMIA FROM HAEMORRHAGE

W Borchardt (*Deut med Woch* March 28th 1930 p 521) records the results of his experiments on young dogs in which anaemia had been artificially produced by the removal of about half their blood In the first series some of the animals were fed with rib marrow others with marrow from the long bones Control animals received a corresponding amount either of fat or of liver extract The basal diet in each case contained a sufficiency of iron (5 mg per cent.) Only the animals receiving the red rib marrow showed a definite increase of weight and their haemoglobin formation was more rapid than that of the others. In the next series the experiment was repeated but the iron content of the diet was reduced to 1 4 mg per cent The result was similar but more striking the dogs receiving the rib marrow regaining their haemoglobin far more quickly than the other

THIS extract from the "Epitome of Literature," published in the "BRITISH MEDICAL JOURNAL," dated May 3rd last, is important as representing, in 1930, a complete justification of the formula upon which

Roboleine
THE FOOD THAT BUILDS THE BODY

has been produced without variation during the past twenty five years

The success of ROBOLEINE is thus due to intelligent anticipation and to consistently maintaining the highest possible standard of manufacture

Medical Practitioners are asked to satisfy themselves of the merits of ROBOLEINE, for which purpose testing samples will be gladly sent upon request.

MONTANA HALL

MONTANA, SWITZERLAND

FOR BRITISH PATIENTS

MONTANA HALL has just been built and will be ready to receive patients on October 27th

For the treatment of Tuberculosis, Diseases of the Chest Asthma, for patients requiring rest in the Alps under strict medical supervision, and for medical conditions in which sun and air bathing are indicated.

The outstanding Feature of Montana Hall is that it is staffed by British Doctors and Nurses and is the ONLY MEDICAL ESTABLISHMENT in SWITZERLAND under BRITISH OWNERSHIP and CONTROL

Quiet situation Magnificent views Admirable walks in the immediate vicinity Accommodation for 70 patients Sound proof rooms Private balconies Hot and cold running water and central heating throughout Wireless (headphones) in all rooms with extensions to the balconies Light signals instead of bells Some rooms with private bathrooms and w c s Fine roof Solarium (partly sheltered and partly open) to which runs a lift capable of taking a bed Public rooms include large dining room drawing room lounge reading room and library billiard room and clock golf room Operating theatre Well-equipped X ray room Laboratory Room for electrical and light treatment Most modern disinfecting and sterilizing plants All facilities for special treatments Night Sister on duty The cooking will be adapted to English requirements

INCLUSIVE TERMS from seven to eleven guineas per week according to the room For further particulars apply to — *The Medical Secretary, Montana Hall Montana Switzerland*

Resident Medical Superintendent HILARY ROCHE M D (Melb) M R C P (London) Tuberculous Diseases Diploma (Wales) formerly House Physician to the Brompton Chest Hospital London Medical Superintendent of the Palace Sanatorium Montana etc

Resident Consulting Physician A M GOSSAGE C.B.E. M D (Oxon) F R C P Consulting Physician to the Westminster Hospital and to the East London Hospital for Children late D M S Ministry of Pensions

MONTANA is situate on an extensive plateau (5 000 feet above sea-level) on the North side of the Rhone Valley This plateau on which there are four lakes and extensive pine forests allows of level walking for some five or six miles For this reason and on account of its high sunshine record (see table below) **MONTANA** is unique among the Swiss Alpine resorts as an all the-year round "curing centre Patients in Montana do not experience the shut-in feeling apt to be produced by residence in many mountain resorts There is protection from North and North Easterly winds

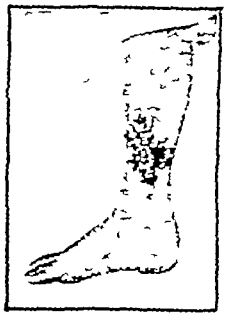
One of the many uses of

Elastoplast

Patent No 253 527

Regd. Trade Mark.



BRITISH MADE

COTTON ELASTIC ADHESIVE in the TREATMENT of VARICOSE ULCER.

THE treatment of this condition has never been satisfactory because treatment has been concentrated on the ulcer, rather than on the underlying cause —viz., the Varicose Veins, which in this condition nearly always lie deep in callous oedema. Local treatment, as with Dressings, Lotions, Light Therapy, etc., are useless except in the mildest cases, but with continuous pressure from Elastoplast. every ulcer, however severe, will heal at a steady average rate of one square inch per week. (Proceedings of the Royal Society of Medicine, May, 1930, Vol 23, No 7, page 1032)

Contrary to all a priori methods, the Elastoplast is placed directly over the ulcer without any dressing intervening or preliminary cleansing, and is changed every 3 to 14 days, according to the rate of accumulation of discharge When the Elastoplast is removed it is amazing to find under the discharge, that tissues which have been indolent maybe for twenty years, in spite of all treatment, have undergone a metamorphosis The ulcer is now flat instead of crateriform, pink healthy granulations replace the glazed ulcer surface, and the blue line of epithelisation appears at the edge of the ulcer, and then nothing is more fascinating than to watch the steady progress of healing as each successive Elastoplast is removed

The patient all the time continues his work and exercise, and is free from pain, and no longer suffers from the insomnia always associated with Varicose Veins

Method of Bandaging

Elastoplast provides even support and compression yet permits perfect mobility

Elastoplast Products are recommended and prescribed by leading surgeons They are already in constant use in most London and many Provincial Hospitals for Varicose Veins, Ulcers, Sprains, Dislocations, Fractures, Surgical Operations, &c.

Introductory trial set with full details of method of treatment will be sent upon receipt of P O value 2/6 by the Manufacturers —

OVALTINE

FOR THE GROWING CHILD

"Ovaltine" is indicated as a means of promoting normal growth and development when the weight of the child under observation is less than that which statistics show a child of the same height should weigh

The physician has only to consider the composition and properties of the product to recognize how suitable it is as a building and reconstructive nutrient

"Ovaltine" is a concentrated extraction of malt milk, and eggs in the form of golden brown granules For tissue growth or repair it provides proteins, mineral constituents adequate energy value, and the Accessory Growth Factors or Vitamins in correct nutritive ratio

Children love the deliciousness of "Ovaltine" and thrive remarkably well upon this complete food It is of unsurpassable value as a meal-time beverage in place of tea, coffee, cocoa or other beverages

SCHERING LTD, 3, Lloyd's Avenue, London, E C 3

Full size trial package free to Medical Practitioners in the British Isles on application to Boots the Chemists, Station Street, Nottingham.

OLIVITA

OLIVE OIL WITH VITAMIN D

Olivita consists of the finest Virgin Olive Oil to which has been added that proportion of Irradiated Ergosterol which gives it a Vitamin D content equivalent to that of Cod Liver Oil

Having investigated the conditions under which Boots Olive Oil is produced in Spain the finest grade of Olive Oil available is guaranteed to be the first pressings from the Olives

Olivita will be found very palatable and can be recommended without hesitation to regular users of Olive Oil

The wide range of usefulness of Olive Oil is well known and members of the medical profession will readily appreciate the further advantages conferred on this product by the incorporation of the sunshine Vitamin D

Recent researches have indicated that substances containing Vitamin D should form part of the diet of all children during the period while the permanent teeth are being calcified Cod Liver Oil is now often given to babies as a regular part of their diet as a good source of Vitamin D and Olivita provides a palatable alternative

Its keeping properties have been thoroughly tested and the uniformity of its vitamin content is controlled by Biological tests

STIMULATING, RAPIDLY ABSORBED, THESE ESSENCES RESTORE VITALITY WHEN SOLID NOURISHMENT IS IMPOSSIBLE

BY APPOINTMENT

RECENT investigation amongst members of the medical profession reveals that 99 *out of every* 100 interviewed recommend Brand's Essences

Containing those essential elements of meat which excite the gastric secretions and make digestion easier, Brand's Essences provide an immediate stimulant when vitality is low and the body too weak to absorb solid food

No effort is required to assimilate them, for they consist only of the pure juices of the finest fresh meats conserved in their natural form, without the addition of any preservatives, colouring matter or gelatine

The delicious jelly is invaluable in dangerous illness whenever a patient is in need of food which can be absorbed without the slightest strain on the digestive organs And in convalescence, Brand's Essences promote appetite—help to win back the desire for solid, strength-building diet and so hasten recovery

Brand's Essences are obtainable at chemists and stores throughout the world in tins and glasses Free samples will be sent to you on receipt of professional card Write Dept F13, Brand & Co Ltd, Mayfair Works, Vauxhall, S W 8

OUT OF EVERY HUNDRED DOCTORS RECENTLY INTERVIEWED 99 RECOMMEND

BRAND'S ESSENCES

(Made only from the finest English Beef, Chicken or Mutton)

Specially indicated in

NEPHRITIS - URÆMIA - ECLAMPSIA - ALBUMINURIA

and allied conditions.

PROMPT and proper diagnosis of kidney conditions is necessary in cases of Bright's disease and all types of renal disorders In nine cases out of ten the administration of a specific capable of producing real results in compensating for the loss of kidney function is also necessary

For more than a quarter of a century Nephritin has been a sheet anchor to physicians in treating such disorders Nephritin Tablets induce a marked increase in nitrogenous waste elimination They reactivate the cells of the kidney increase urinary secretion, and induce a greater output of urea.

Given in sufficient dosage these tablets produce marked results, and restoration to normal is quickly stimulated. They are invaluable also as a prophylactic in renal complications of infectious diseases and during pregnancy The tablets are composed of the hormones of the normal kidney as they appear in nature—*absolutely unaltered*

DIURETIC RE-ZYME TABLETS

Manufactured by

REED AND CARNRICK

Pioneers in Endocrine Therapy

Jersey City, New Jersey

Builds up in underweight conditions and provides a perfectly balanced, highly nutritive diet for growing children

TO the problem of the "underweight" child Horlick's Malted Milk provides a convenient solution

For many years it has been successfully used by the medical and nursing professions for fast-growing children, for invalids, for expectant and nursing mothers — in all cases where it is particularly important to sustain strength and replenish natural energy quickly

Excellent results obtained by adding Horlick's to the diet of growing children have been *strikingly recorded in many thousands of letters* written by parents and members of the medical profession

Made from fresh, full-cream cows' milk, selected wheat and malted barley, Horlick's Malted Milk constitutes a perfectly balanced food — containing fat, proteids, and soluble carbohydrates in correct nutritive ratio

The vitamins of its constituents are unimpaired by the Horlick process

Horlick's contains neither cane sugar nor unaltered starch, but presents in proper proportions a sufficiency of valuable malt sugars, for which children have a greater toleration. Moreover, Horlick's is partially pre-digested during manufacture, thereby assuring perfect assimilation.

In addition to its important body-building qualities, Horlick's has the advantage of being an extremely palatable beverage Most children like the natural flavour of malt and will drink Horlick's with pleasure And it is now obtainable also in a new Chocolate Flavoured form — identical in constituents with the original Horlick's, but with fine chocolate added

Horlick's Malted Milk (both forms) is obtainable everywhere in sealed glass bottles, at 2/-, 3/6, 8/6 and 15/- Also in tablets

Further details and supplies for tests may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks

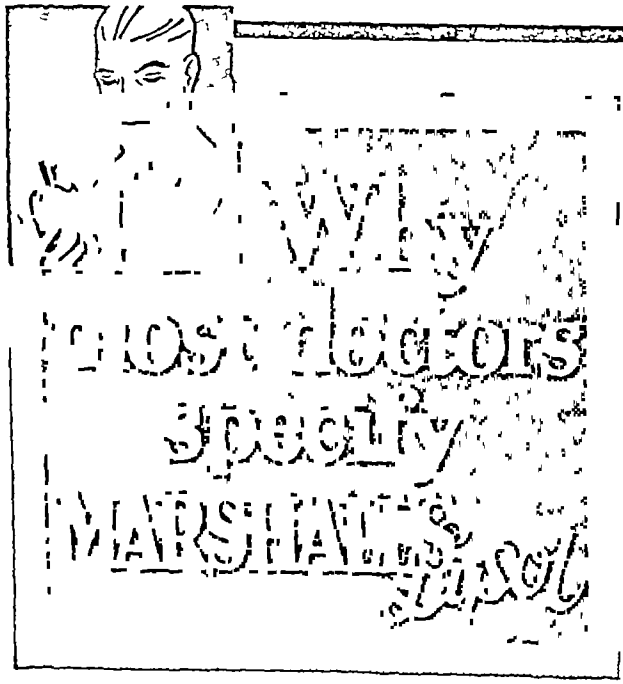
A palatable combination of Lactose & Dextrin

for changing the intestinal flora

Lactose 73%, dextrin 25%—that is the proportion in which these carbohydrates are combined in this new food for changing the intestinal flora Both are more slowly absorbed than other carbohydrates, and both are able to reach the colon in sufficient quantity to cause a luxuriant growth of protective flora An acid reaction of the intestinal contents unfavourable to toxic organisms is thus produced —Lacto-Dextrin being highly efficient in promoting the growth and development of both B acidophilus and B bifidus in the colon In this pure carbohydrate food both lactose and dextrin are presented in a palatable and agreeable combination

PSYLLA



an accessory for use in conjunction with Lacto-Dextrin

Where bulk and lubrication of the intestinal tract is also required, the use of BATTLE CREEK Psylla (Plantago Psyllium) is invaluable as an accessory The small brown seed when in contact with water swells into a soft gelatinous mass and acts most effectively both as an emollient and intestinal evacuant

Samples and literature of both these intestinal products will be sent to members of the Medical Profession on request to Coates & Cooper, 41, Gt Tower St, London, E C 3, Sole Distributing Agents for the United Kingdom and Irish Free State

LACTO-DEXTRIN

Manufactured by the BATTLE CREEK FOOD CO, Mich, U S A.

MOST doctors say "Marshall s" automatically when they specify Lysol

The reason is simple the necessity vital

There are many brands of Lysols and many liquids known as "Lysol Solution Many of the former are impure, caustic, irritant Two bottles of the same brand may vary enormously in quality So-called "Lysol Solutions are in most cases only 1/16th as strong as Marshall s Lysol

Marshall s is the only Lysol made from the original formula and to the original specification Every bottle of Marshall s Lysol is of a uniform high quality

Marshall's Lysol really is an efficient and reliable antiseptic and is absolutely harmless when used as directed, but must never be used undiluted

Sample sent upon request to members of the Medical and Nursing Professions

MARSHALL'S Lysol

LYSOL LIMITED RAYNES PARK LONDON S W 20

CONTRAMINE

The importance of chemotherapy in modern medicine has been emphasised by its selection as a subject for discussion at two independent Sections of the recent meeting of the British Association

Contramine is a typical chemotherapeutic drug its administration produces encouraging results in the treatment of the chronic complications of gonorrhoea and in chronic rheumatism arthritis and fibrositis Recently Contramine has been used also as an adjunct to antitoxin in the treatment of diphtheria (*Lancet* Sept. 13th 1930 p 597)

Contramine is supplied in solution in ampoules ready for intramuscular injection it is obtainable from all the principal pharmacists

"MODIFIED MILK IN INFANT FEEDING"

The above-named booklet of 64 pages will be gladly sent to members of the Medical Profession

The booklet shows how

Mellin's Food

is very readily adaptable to the needs of both the normal infant as well as the infant requiring a special modification of diet It contains suggestions respecting milk modifications for use in cases of constipation, marasmus diarrhoea etc

It shows the analysis of the mixture suitable for infants of various ages the weight of the various food constituents and their calorific value

Write for a copy to-day

MELLIN'S FOOD Ltd., LONDON, S E.15

PUERPERAL MORTALITY

IT is now considered that the majority of cases of puerperal sepsis are caused by the introduction of streptococci from without during the course of labour This is a cause which should be preventable by the use of an efficient germicide

The germicide in common use in obstetrics has been lysol, but it has been shown recently that the dilution of lysol which can be relied on to kill streptococci is far stronger than the tissues can stand

Considerable advantages are afforded by the use of Monsol germicide, which is bland and emollient in action and, having 10 times the germicidal strength of lysol on streptococci, can be safely used at a strength which ensures the destruction of these bacteria

In addition, Monsol has a particularly selective action on the strain Haemolyticus which is considered one of the principal causative agents of puerperal sepsis

Moreover the presence of organic matter affects the germicidal action of Monsol much less than that of any other antiseptic known, while at therapeutic concentrations Monsol is absolutely non-irritant even to mucous membranes

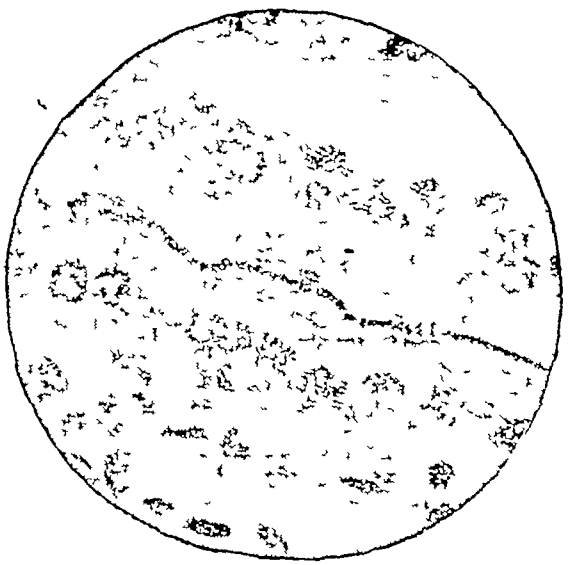
Streptococcal Infection in relation to Vitamin B Deficiency.

Experiments were undertaken in an endeavour to trace how the Colon Bacillus found its way into the urinary tract

We had proved in earlier work that atrophy of the whole of the muscular and mucous coat of the digestive tract took place when animals were fed on food deficient in vitamin B Following upon this atrophy and intestinal stasis we thought it might be possible to trace infection via the intestinal canal, so we fed certain organisms to animals whose diet was deficient in vitamin B and also to a number of control animals



The test animals were fed on a completely deficient vitamin-B diet for a month and then on a partially deficient diet for a further eight weeks To these partially deficient animals and to the Bemax-fed animals were given living cultures of various organisms, pneumococci to some, staphylococci to others, and to the remaining animals streptococci grown from a tooth removed from a patient suffering from rheumatoid arthritis Pure cultures were made of each of these organisms in broth

The animals were given no liquid for twelve hours and were then given the broth containing large cultures mixed with milk, which they drank readily The cultures were made up to ten thousand million organisms to the c.c. of broth one c.c. of this culture was given in oatmeal with fresh milk

The control animals were fed on the same diet as the test animals except that Bemax was included. Living cultures were similarly given to these controls

Four days after taking the living cultures the control and test animals were killed by the administration of chloroform, the abdominal cavities were immediately opened and portions of the digestive tract removed and sections made in the ordinary way

In all the Vitamin-B deficiency (non-Bemax) animals we traced the organisms having penetrated through the mucous wall, whereas in the "Bemax-fed" animals we found that no organisms had penetrated the mucous membrane and only very few were found in the lumen of the intestine, whereas in the "non-Bemax" animals (vitamin-B deficient) the whole of the intestinal tract was loaded with organisms

The illustration is a reproduction of a section from the vitamin-B deficient (non-Bemax) animal and shows streptococci within the lacteal They have penetrated through the mucous surface and are lying in the lymph channel

Detailed reports of further research work will be sent on request to members of the medical profession

BEMAX

The natural vitamin Tonic Food.

A Free Full Sample of BEMAX for personal use and full reports of the laboratory experiments will be sent to any medical practitioner on application to

THE BEMAX LABORATORIES,
38, DANEMERE STREET, LONDON, S W 15.

Alternative Methods in Prophylaxis and Treatment of

CORYZA

DETOXICATED ANTI-CORYZA VACCINE. This Vaccine has been used with great success for several years Its outstanding feature is the absence of reaction, which makes it especially useful for hyper-sensitive patients

ORDINARY ANTI-CORYZA VACCINE. Some Practitioners consider that a slight reaction has definite therapeutic value, and this type of Vaccine has been prepared to meet their requirements It has the advantage of very low price.

ANTI-CORYZA VACCINE SPRAY (For local application to the nose and throat) For patients who object to Vaccine treatment by subcutaneous injection, and for children, this Local Immunity Product is particularly indicated An additional convenience is that frequent attendances by the patient for injections are unnecessary.

Additional information regarding the above products will gladly be supplied to any Practitioner who writes to The Vaccine Department, Genatosan Ltd, Loughborough, Leicestershire

The confidence of the MEDICAL PROFESSION.

Benger's Food has gained its unique position not by extravagant or sensational advertising but by the constant recommendation of medical men and women To-day it is universally used not only at home but throughout the world Few foods have so enjoyed the approbation of the Medical Profession for over 40 years

Benger's Food differs from all other foods in that it is especially prepared to adjust fresh cows' milk or cows' milk and water so as to suit the condition of any patient. While it is largely used as a routine treatment in all cases of disordered digestion the following comments, which have been recently made by Doctors, indicate some specific uses to which Benger's Food has been put

DYSPEPSIA

"routine food in all cases of dyspepsia and disordered digestion"

"used for invalids and all gastric cases"

INFLUENZA.

"very largely used for Influenza in all its forms"

CANCER

"invaluable for cancer of the throat"

"cancer of the stomach—doing well on Benger s Food."

THE AGED.

"very beneficial for man of greatly advanced years"

"invariably used for invalids and aged persons"

A Physician's Sample will be sent post free to any member of the Medical Profession making application to the Proprietors—

KUFIC INSCRIPTION FROM MOSQUE ASSOCIATED WITH FIRST ARABIAN HOSPITAL IN EGYPT.—The building of the hospital founded by the generous and enlightened Caliph Ibn Tulun was carried on with the greatest enthusiasm, uninterrupted by the frequent political and military disturbances. Expense was not spared; the hospital buildings with the mosque and two baths one for men and the other for women, seem to have cost the equivalent of £28,000. Ibn Tulun provided for their daily upkeep by surrendering several estates and the revenue derived from the slave market. Every Friday the Caliph went himself to inspect the physicians and medicaments to visit the sick and insane. So well were the sick treated that we are told later of much feigned sickness for the sake of the "tender chicken, pastry sherbet and cakes of all kinds with which they were regaled.

DAME A. LOUISE McILROY, M.D., D.Sc., L.M.,

PROFESSOR OF OBSTETRICS AND GYNAECOLOGY, UNIVERSITY OF LONDON; ROYAL FREE HOSPITAL.

A considerable amount of discussion has been taking place in Britain as to the necessity for the provision of treatment for pain in so-called normal labour. Among medical practitioners the subject is a somewhat controversial one. It is obvious that one of the first principles of treatment in medicine is that when pain is present it should be relieved as soon as possible. Some, however, maintain that the pain of childbirth is an exception, and that any effort towards its relief is against the will of God. Had Sir James Simpson been influenced by the ecclesiastical arguments of his day we might not have had the benefit of chloroform narcosis in obstetrics or in surgery. In obstetrical practice it should be an axiom that pain should be relieved in every case when it does not interfere with the safety of the mother or child.

Anaesthesia in cases of complicated labour is a necessity when operative measures are indicated. This is not a controversial subject. It is in cases where labour, although looked upon as normal, is accompanied by pain and suffering that women now demand relief. How far with safety can we give freedom from pain? A painless labour can never be safe, but a very considerable modification of suffering is within the scope of treatment of every practitioner. In the past little attention has been paid to the subject, but now women refuse to submit to the sufferings borne by their mothers and grandmothers. Not only do they demand relief for themselves, but in London a large and influential group of members of the public is providing resident anaesthetists for various maternity institutions, in order that the patients should be given relief, and that students and nurses should be trained in the advantages of childbirth conducted by humane methods of treatment. The agony of child bearing is almost worse than any other suffering, and there must be some reason why the average practitioner does *so little for its relief*. *In the first place*, so little is known as to the risk of the administration of drugs in labour. Also, if analgesics and anaesthetics are to be given they entail an additional expenditure of time on the part of the medical attendant. They also involve skilled assistance in many cases, and the expense may be almost prohibitive except for hospital patients and those among the well-to-do. But the question must be discussed and some solution found, since the public is insistent in its demand.

Sedatives tend to prolong labour rather than shorten it in many cases, by diminishing the expulsive forces of the *uterine contractions*. This adds to the risks of labour for the mother, but more especially for the child. We must therefore have a thorough knowledge of the action of sedative drug and only employ those which give the maximum of relief with the minimum of danger. The problem is intensified by the fact that childbirth differs from a surgical operation. Much depends on the temperament of the patient, her environment, and her uterine contractions. The process of labour is prolonged in comparison with surgical conditions and two lives have to be considered. Some women have little or no suffering, *others under the same obstetrical conditions* suffer acutely. Each case must be treated individually and experience and caution are necessary.

In the Report of the Government Departmental Committee on the Training and Employment of Midwives, which was issued in 1929, it was urged that some professional body should make a pronouncement as to the advisability and place in labour not only of anaesthetics but also of analgesics and sedative drugs in general. A response was made by the British Medical Association, and a report of a committee was issued in April, 1930. The main expression of opinion was that of caution, and that any further expansion of the uses of anaesthetics and analgesic drugs in non-operative cases would be associated with danger to the mother and child. The question was left very much as it had been. The report may be of value in view of the present public agitation favouring the indiscriminate use of anaesthetics in all midwifery cases, but it does not give much help or encouragement to those of us who are anxious to relieve suffering whenever it is possible in obstetrical practice.

The opinion of this committee will be referred to later with regard to the use of special drugs. It is by frequent discussions between representative members employed in the practice of anaesthetics in obstetrics and in general practice that we shall in time gain useful information as to the most suitable methods to employ, we may eventually find the perfect method which will give complete relief without any risks to the two lives concerned.

The problems for discussion are the management of the *stages of labour*, *the most suitable analgesics and their* dosage for the first stage and those for the second combined or not, with anaesthetics, the differences between institutional and domiciliary practice and the expense involved. We have also to consider the primary question is relief of pain necessary in so-called normal labour? What are the dangers, complications, and the effects upon uterine contractions, retraction, and post-partum haemorrhage?

Although analgesia and anaesthesia may involve risks to the mother and child I am firmly convinced that a considerable amount of our maternal death rate is due to lowered resistance from excessive fatigue, shock, and sepsis, the result of withholding relief during labour. In my clinic, where for the last nine years the use of sedatives, and, when necessary, light anaesthesia for the second stage and during delivery, is almost the routine method of treatment in ordinary labour cases, the patients are remarkably free from fatigue at the end of labour, and in a few hours show very little trace of their experience in the labour room. Mental suffering especially fear, has an effect in lowering the resistance to shock and to sepsis. I am convinced that better results in the management of labour and in the reduction of maternal mortality will be gained by much greater attention to the relief of suffering in labour. Puerperal insanity can to some *extent* be prevented by the abolition of anxiety and suffering.

ANALGESIA IN LABOUR

Analgesic or sedative drugs are administered in the first and second stages of labour, since pain is relieved without the loss of consciousness in most cases. Anaesthetics are employed to abolish consciousness, and they are used intermittently in the later second stage, while deeper anaesthesia is used during delivery. Deep anaesthesia is employed where operative measures are necessary.

In the first stage of labour no sedative, as a rule, is required until labour has become established and the patient is conscious of the discomfort of the uterine contractions. The general condition of the patient has to be considered, and also whether she is suffering from pain or only from anxiety and dread of the ordeal in front of her. Pain is felt in the back and abdomen and she is restless and disturbed. The drugs most usually employed in the first stage are chloral hydrate, potassium bromide, opium and its derivatives, scopolamine and numerous other sedatives, in combination or alone.

Chloral Hydrate

Chloral hydrate in doses of 10, 15, or 20 grains is given by the mouth, or by the rectum in some cases. It is repeated as required. This is the rule for most sedatives in labour, no fixed time can be laid down, since patients and uterine contractions vary so much, but when pain is not present no sedative is necessary. Chloral hydrate is

[3639]

Made in opening a discussion in the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association in Winnipeg, 1929.

usually combined with 10 to 30 grains of potassium bromide given in sweetened water There is almost no risk to the mother or foetus, the cervix is softened, and labour progresses although the patient may be asleep The doses can be repeated during the second stage

It is said that free bromine in the stomach may cause undue sickness Plenty of water should be given during labour in all cases Sometimes the effect of these drugs is slow, or of little benefit, and other drugs have to be resorted to

Opium

Opium and its derivatives have been used from time immemorial This drug is an ideal sedative from the patient's point of view, inducing restful sleep, arousing no anxiety or discomfort, and aiding dilatation of the cervix, and therefore exercising a beneficial influence on the progress of labour It is most valuable in the slow dilatation stage in primigravidae It rests a tired uterus, and contractions begin again with renewed energy Opium itself, in the form of the tincture or liquor, is not pleasant to take, and it may cause excitement or sickness Its derivatives, such as morphine sulphate, omnopon or opoidine, panopon, are much more efficacious in their results if given hypodermically in doses of 1/6 to 1/4 grain Dissolved in a 50 per cent solution of magnesium sulphate and injected into the buttock the effect is prolonged The magnesium sulphate can be repeated without the morphine, and the sedative effect is prolonged

With such an ideal sedative, why try any other? It is said that the effect of morphine upon the foetus is fatal in some cases, and its administration is limited to the first stage, or at least not within three hours of delivery I have used omnopon for many years in the first and early half of the second stage of labour, and I have rarely seen any ill effects from its use The foetal heart requires constant auscultation during its administration in the second stage It accelerates labour, and frequently obviates operative intervention It relaxes the pelvic tissues, and prevents the patient inhibiting her muscular activities, but it requires to be given by experienced practitioners Browne, in the examination of 300 foetal post-mortem examinations, found that four deaths could be traced to morphine administration in labour

Scopolamine-Morphine

Scopolamine-morphine—twilight sleep—introduced by Kronig and Gauss in Freiburg in 1907, caused a wave of enthusiasm among obstetricians, but its use was so mixed up with advertising commercial interests outside the profession, and so little was known as to its effects and dangers, that the number of practitioners who still employ this method is somewhat diminished It is not used extensively in Britain America, France, or in Germany The advantages of the combination of these drugs are that pain is relieved, and the patient has no recollection of any suffering There is no marked ill effect upon the patient The uterine contractions persist, progress in descent of the foetus takes place, and there is no additional risk of post-partum haemorrhage The third stage of labour is shortened The scopolamine-morphine must be given early in labour, since it is more difficult to narcotize the patient if she has had experience of severe pain Most obstetricians give only the initial dose of morphine (1/6 or 1/4 grain) and repeat the scopolamine in varying doses—1/150, 1/200, or 1/450 grain—as indications arise The chief indication is obtained by means of testing the patient's memory of various objects given to her to recognize Scopolamine can be repeated up to delivery

The disadvantages of this method are numerous It is essentially a form of treatment for the hospital or nursing home since it requires isolation, complete quietness, and skilled and constant attention There is sometimes considerable excitement on the part of the patient, which may cause anxiety to her relatives if the confinement is conducted in her own home She may suffer from thirst, headache, dizziness, and eye symptoms

The chief objection is that the foetus may become asphyxiated and stillbirth may result, most practitioners put this down to the initial dose of morphine When successful the method seems ideal, but it can never become widespread, since it involves too much expenditure of time on the part of the practitioner, unless he has a special department with an experienced staff

Scopolamine-morphine is not suitable if the labour is prolonged, or if operative delivery is necessary Hyoscine is sometimes substituted for scopolamine, but it tends to prolong labour and to cause post-partum haemorrhage A modified method of giving small doses of scopolamine during labour relieves pain to a great extent without inducing loss of memory, this does not require such constant attendance, and gives good results

Adaline

Adaline is valuable, given in doses of 5 to 10 grains by the mouth I have had considerable experience of its use, and have seen no ill effects It is easy of administration, and relieves pain in both stages of labour

ANAESTHESIA IN LABOUR

Although we look upon anaesthetic drugs as those which are usually administered by means of inhalation, there are other more local methods of obtaining relief from pain in childbirth, just as there are in surgery It is somewhat difficult to classify the various anaesthetic drugs, since they differ according to their methods of administration

The chief inhalation methods are those by means of chloroform, ether, and nitrous oxide gas

Chloroform

The administration of chloroform in surgical and obstetrical practice seems to be more or less geographical In Scotland, the home of Simpson, it is more used than in England, where ether is the anaesthetic of choice Some practitioners prefer ether for surgical operations, but show a partiality for chloroform in obstetrics It is said that a pregnant woman is very tolerant of chloroform inhalation, and that it does not require such a skilled administrator as in the case of surgical conditions This is probably due to the fact that chloroform anaesthesia is, as a rule, light and intermittent during labour—*a la reine* Indeed, during the second stage, chloroform can be given by the patient herself in some cases The usual method is to give a few drops on a mask and let the patient gently inhale it As delivery approaches, the quantity administered is increased according to the degree of anaesthesia required During expulsion, the most painful part of labour, complete anaesthesia may be necessary in some cases In the third stage of labour it is not necessary to give an anaesthetic unless manual removal of the placenta is to be undertaken For the satisfactory repair of lacerations it is, as a rule, necessary to anaesthetize the patient

Chloroform has a soothing effect upon a nervous patient when given only in minute quantities in labour It often causes the pains to become more regular, and it relieves spasmodic contractions of the perineum and other structures due to the fear of pain on the part of the patient The more rapid advance of the presenting part can be observed in cases of light chloroform anaesthesia During delivery more control is obtained, and therefore the risk of lacerations is diminished The effect of an anaesthetic relieves to a great extent the anxiety of the patient's relatives

The disadvantages of deep chloroform anaesthesia are difficult to estimate, since other factors such as operations and complications, are usually involved The uterine contractions may be diminished or abolished with the consequent prolongation of labour and the possibility of post-partum haemorrhage Chloroform is contraindicated in cases of liver involvement, such as acidosis, toxaemia, and hepatic atrophy In eclampsia chloroform is given to allay convulsions, but, if there is any serious liver involvement, its administration is accompanied by risk, and chloroform poisoning may ensue In cardiac conditions chloroform may cause collapse and death, this is more frequent after delivery than during labour The foetus is not much affected by chloroform unless the administration is prolonged or deep It is said that chloroform is partly eliminated by the expulsion of the placenta It should not

be given in a room with a gas fire since decomposition of its elements may occur and death from poisoning result

The committee of the British Medical Association recommends the use of pituitrin to counteract the paralysing effect of chloroform upon the uterine contractions In my own experience this drug is dangerous in any case where there is delay in the second and third stages of labour Its uses are mainly for haemorrhage after delivery of the placenta, and as a means of sensitizing the uterus in order to bring on labour

Ether

Ether is preferred to chloroform by many practitioners as it is said to be safer this applies more to general surgery and deep anaesthesia than to midwifery practice Extensive use is made of it in England, and especially in cases where chloroform is contraindicated, it can be given by the patient herself in small doses Ether is pleasant to take, and often acts as a stimulant to the heart it does not, as a rule, diminish uterine contractions, and is useful in cases of operative intervention such as forceps Caesarean section and for the repair of lacerations It has no bad effects upon the foetus if its administration is not too prolonged or deep The disadvantages are that it is sometimes slow in action, and needs a special apparatus and a skilled administrator The chief drawback is its irritating effect upon the respiratory passages it is therefore unsuitable if pulmonary complications are present or there is oedema of the lungs as in nephritis Some of the risk can be reduced by giving ether in a warmed apparatus, but it causes more sickness than chloroform Ether is inflammable, and care must be taken in domestic practice or in operating rooms where electric appliances, such as the cautery, are in use Sometimes a mixture of alcohol, chloroform, and ether is given, but not so frequently as in surgical work

Cwathmey of New York has advocated the instillation of an emulsion of ether into the rectum during labour in combination with the intramuscular injection of morphine in a solution of magnesium sulphate This method has gained a number of supporters, and in some cases gives excellent results which improve as the technique becomes more perfected it is inexpensive, and is easily carried out in a private house The instillation takes time, and undue excitement on the part of the patient may follow it There is danger of irritation and even of sloughing of the rectum if the ether emulsion is not properly prepared The amount of absorption of ether must vary to some extent, and cannot be regulated in the same way as by the inhalation method

Nitrous Oxide

The administration of nitrous oxide gas and oxygen is undoubtedly the most ideal method of obtaining anaesthesia in midwifery practice, it is safe relieves pain, and does not interfere with the progress of labour It may be employed during uterine contractions, and continuously towards and during delivery It has *no harmful effects* upon the foetus. After birth, before the cord is severed, oxygen alone may be given in a case of asphyxia The after-effects of gas and oxygen are negligible This method is especially useful in short operations, such as induction version, forceps delivery, and repairs It is safe in toxic cardiac, and pulmonary complications It is recommended to begin with gas and oxygen, and to decrease the gas as each labour pain nears completion The disadvantages are that the apparatus is expensive and cumbersome for private practice a skilled anaesthetist is necessary Sometimes the patient becomes excited and difficult to anaesthetize If there is headache after the recovery of consciousness the mixture has contained too much nitrous oxide

Ethylene

A mixture of equal parts of ethylene and oxygen has been advocated lately by some American obstetricians (de Lee Bleyis) There is said to be no excitement at the induction period is short, and it is safe in cardiac cases It has no irritating effect upon the lungs or kidneys It is useful in light intermittent anaesthesia and can be supplemented by ether for delivery It has no ill effects upon the foetus unless prolonged Its chief fault is that it is highly explosive

Local Anaesthesia

Local anaesthesia is advocated by some obstetricians more especially for the relaxation of the tissues of the pelvic outlet Rose, who employs novocain in both stages of labour, gives intradermal infiltration of the abdominal wall in order to abolish the pain of the skin reflexes in the second stage he injects it slowly into the perineal structures He considers that lacerations are usually prevented, and that, if they occur, their repair is easily effected

De Lee employs procaine combined with adrenaline as a local injection in Caesarean section operations Browne uses local anaesthesia entirely for the immediate repair of the perineum injecting 4 to 6 drachms of a 2 per cent solution of novocain with 1 minim of 1 in 1,000 adrenaline solution to each drachm of novocain The infiltration of the perineum and vagina is obtained by a hypodermic needle Perfect relaxation and anaesthesia result without the discomforts which follow inhalation methods

Spinal Anaesthesia

Spinal anaesthesia is employed in surgical practice and also in midwifery to some limited extent it does not lessen uterine contractions or interfere with retraction, and therefore does not cause post-partum haemorrhage It relieves pain by paralysing the pelvic area There are no toxic effects upon the liver or kidneys, and it does not seem to harm the foetus Burns especially advocates its use in Caesarean section, in cardiac cases It has been found to give good results in cases of forceps, version and breech deliveries It requires a skilled administrator, especially in obstetrics, and in some cases its effects are very variable Until it has been more widely employed it is difficult to give an opinion on its merits in midwifery practice, but there is no doubt that it has a place in cases where inhalation methods are contraindicated It is not always sufficiently prolonged in its effects in the case of a primigravida Headache is a symptom but this can be prevented to some extent by using a very fine short needle for injection The drugs most frequently employed are stovaine or novocain, cocaine is considered dangerous by most obstetricians Much of the success of the method depends upon technique and the injection of the drug low down in the cord so as not to interfere with the uterine contractions

Conclusions

Each maternity case must be given individual attention with regard to the most suitable sedative and anaesthetic to be employed The age, parity, temperament general health, and complications if present, must all be carefully considered Obstetrical anaesthesia is not quite comparable with the surgical form The pain is prolonged, and has to be combated with sedatives as well as with anaesthetics the effect of these sedatives must be taken into consideration when an anaesthetic is decided upon

Light anaesthesia is of little use in surgery, while it is generally employed in midwifery practice except in cases where operative intervention is required The action of the uterus must be maintained, and haemorrhage after delivery must be prevented as far as possible The expenditure of time with its consequent financial complications, is a consideration It is desirable that private patients should have the continuous attendance of the practitioner during labour if sedatives or anaesthetics are to be given, just as in hospital practice yet it is impossible to demand this unless adequate financial compensation is made by the patients for the loss of practice elsewhere

In surgical practice only one life is involved In midwifery the interests of the child are of great importance in uncomplicated cases where the only consideration for treatment is the relief of pain to the mother Perhaps the safest sedative is chloral and potassium bromide, and the safest anaesthetic is gas and oxygen from the point of view of the foetus

It is a common mistake to carry out violent methods of artificial respiration if the infant does not breathe immediately after birth We have to remember that it is narcotized to some extent and requires time to recover, warmth, rest and clearance of its respiratory passages are sufficient in most cases of delayed respiration, but CO_2 and oxygen should be given if there is any undue delay

Many an infant loses its life from misguided methods of restoring animation, such as bathing and artificial respiration

In England, where there is so much discussion at present as to the advisability of every woman in labour having relief from suffering, the question is, What is to be done about the patients under the care of midwives? These number about 60 per cent of all the cases of the country Are these patients to be excluded from all methods of relief from painful labour? Are they to be attended by an anaesthetist, and, if so, who is to bear the expense? If midwives are to be permitted to give sedatives, or even anaesthetics, it will involve general training in surgery and medicine and special training in sedative administration This is a real problem, and the opinion of the medical profession is divided

There is room for much reform in the management of labour by medical practitioners, and perhaps that is the first step to be taken The agony suffered by parturient women is one which has called for relief throughout the ages, it should appeal to every humane individual in the medical profession

RADIOGRAPHY DURING OPERATION FOR RENAL CALCULUS

BY

R J WILLAN, M V O, M S, F R C S,

SURGEON, ROYAL VICTORIA INFIRMARY, NEWCASTLE-ON TYNE

(With Special Plate)

Is a so-called recurrent renal calculus really a recurrence, or is it a case of a stone, or a fragment of a stone, being left behind at the initial operation? Fortunately it is not common to have a recurrence, but cases do recur Further, what ultimately happens to a kidney which is traumatized during the operation of nephrolithotomy?

For some years, whenever *x*-ray facilities have been available in the operating theatre I have taken the opportunity of *x*-raying an exposed kidney which was either known to contain a calculus or was suspected of containing a calculus which did not show up on an ordinary radiogram My object has been twofold first, to locate accurately the site of the stone so as to damage the kidney as little as possible during its removal, secondly, to be certain by a further radiogram, after removal of the calculus, that no fragment has been left behind Even a small calcareous fragment left behind is sufficient to form the nucleus of a further stone

Where a calculus is concealed in a calyx it may not be possible to palpate it either through the solid tissue or through the pelvis of the unopened kidney I feel certain that when the solid part of the kidney is incised for an adequate search—usually so that the *inside* of the renal pelvis can be palpated—the subsequent suturing up so constricts the blood supply that the incised portion of the kidney becomes functionless

The *x* ray apparatus which I use for this purpose is an ordinary Dean 16 inch coil set It is kept entirely for work necessary during operations, and when out of use it is housed in a large airtight cupboard in the operating theatre It can be mounted and ready for use in three minutes

When operating in a renal case my patient lies on the sound side, with the diseased side uppermost After exposure of the kidney, and when all bleeding points have been secured, so that the field is as dry as possible, the film, in its paper covering, is wrapped in a dry sterile cotton cylinder—that is, an arm sleeve—and placed in position The film is pushed down into the wound in the case of a short renal pedicle, but there is usually no difficulty in persuading the kidney to lie upon the film while the skiagram is being taken An exposure of one second has always sufficed It is emphasized that the operation field must be dry, otherwise the film is ruined by the damp, further that sepsis may permeate through the blood-soaked sterile towel and result in a progenic wound [illegible] A technician stands by and develops the film, which has usually been available in three minutes, never longer than five minutes, after its receipt I have seen the method used of trying to view the exposed kidney through a fluorescent screen The technical difficulties of screening, however, are greater, for the theatre must be darkened, the surgeon's eyes take time to become accustomed to the darkness before he can see adequately, and small calculi are apt to be missed In my opinion, taking a film is preferable, as it is much more certain

When the calculus has been located, and its size and shape noted, it is removed by the smallest possible incision After its removal another radiogram is taken by a similar technique to verify the complete removal of the stone or stones The kidney tissue incision is closed by catgut sutures and the wound area drained by a tube

I have chosen four typical cases

1 A case of renal colic in a very stout female, where ordinary radiography and pyelography failed to disclose a calculus X-ray examination of the exposed kidney revealed a stone and its location After nephrolithotomy a further radiogram showed normal shadows

2 A calculus, previously seen by *x* rays, was accurately located by radiography of the exposed kidney at operation, a further radiogram was taken of the exposed kidney after nephrolithotomy

3 A case of multiple calculi located at operation by *x* rays where, after all the calculi had been thought to be removed, a further radiogram of the exposed kidney disclosed a calculus left behind

4 Eight years previously a small renal calculus had defied the surgeon at a nephrolithotomy until the kidney had been slit up from pole to pole Pyelography showed that this traumatized kidney had become functionless, owing to strangulation of the blood supply by the catgut sutures employed in sewing up the kidney

Particulars of these cases are recorded below

CASE I

On September 6th, 1928, M W, aged 50, a very stout female, was admitted for investigation of acute attacks of left-sided typical renal colic Radiography failed to show any abnormal shadows, despite good radiograms Cystoscopy showed a basal cystitis with ulceration in front of both ureteric orifices, but particularly the left sided one The ureters were catheterized, and subsequent distensions of the left renal pelvis caused the acute pain of which she had complained

Pus cells were obtained in the urine withdrawn from each kidney, the phenolsulphonephthalein excretion from the right kidney was 7½ per cent, compared with only 1½ per cent from the left kidney The blood urea was 60 mg per 100 c cm The phenolsulphonephthalein test failed owing to only a portion of the dye reaching the vein Pyelography showed a normal right pyelogram with a small degree of hydronephrosis of the left side

A diagnosis of uric acid calculus was made, and the left kidney exposed by operation A radiogram (Fig 1) showed a small uric acid stone in the middle of the lower pole of the kidney The calculus was removed through a small incision to the cortex A further radiogram (Fig 2) showed that all the fragments had been removed The renal cortex was sutured with catgut, the patient made an uneventful recovery, no urine ever leaked from the wound

Had the first radiogram of the exposed kidney failed to show a stone, the kidney of course would not have been opened

CASE II

L W B aged 36, was admitted with a history of right sided renal colic, from which he had been suffering for three years It prevented him from carrying on his practice as a dental surgeon *X* rays showed a shadow in the area of the right kidney His blood urea was 60 mg per 100 c cm

Cystoscopy showed a subacute cystitis Urine obtained from each kidney by ureter catheterization was found to be free from pus on microscopic examination Distension of the renal pelves by a measured quantity of fluid revealed that the capacity of the right side was three times greater than the left side The phenolsulphonephthalein excretion of the right kidney was only 7½ per cent, that of the left was 12½ per cent Pyelography disclosed a normal left side, with hydronephrosis on the right side Further, the shadow previously seen on the right side was incorporated in the pyelography shadow

After exposure of the kidney the calculus could not be felt The radiogram showed it to be in an upper calyx (Fig 3) It was removed, along with a small calcareous flake Another radiogram showed absence of any foreign body (see Fig 4)

He made an uneventful recovery, without leakage of urine from the wound

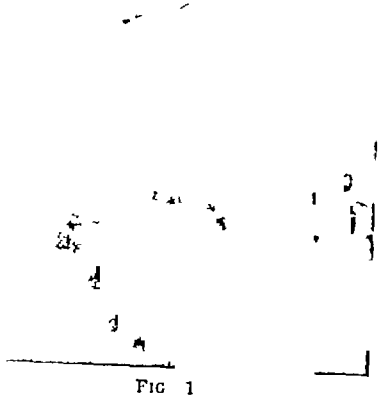

FIG. 1.

FIG. 2.

CASE III

F. C., aged 28, was admitted on October 22nd, 1928. For four years he had been suffering from attacks of acute left-sided renal colic which came on every four or five days. He had intermittent frontal headache of the morning type and had lost a great deal of flesh. The bloodurea index was high and the phenolsulphonephthalein excretion was low. The specific gravity of his urine was 1005 and it contained albumin. X rays showed a number of shadows in both renal areas. Pyelography showed that the shadows filled with the pyelogram shadows, a diagnosis of renal calculus was certain.

A left-sided nephrolithotomy was recommended because of the severe pain, but it was clear that the total amount of renal tissue was so diminished that nephrectomy was contraindicated. An operation was a serious undertaking and had to aim at the least possible damage to the kidney.

The left kidney was exposed and found to be twice its normal size. None of the calculi could be felt through the renal tissue. X rays (Fig. 5) showed multiple stones also their location. The incised part of the kidney showed marked deficiency of the normal renal tissue which was largely replaced by fibrous fat. The stones were extracted and it was thought that all of them had been removed. A further radiogram showed, however, that one rounded stone remained. It was easily located and removed. (Fig. 6—the small shadow near the pelvis was a fault on the film; it does not show on the previous radiogram.) The removed calculi were composed of uric acid.

The patient stood the operation well but died from uraemia eleven days after. A post mortem examination revealed that all calculi had been removed from the left kidney, while the other kidney contained multiple calculi and was in a similarly severely damaged condition. Despite the fact that the operation was performed entirely with as little damage as possible to the kidney, the total renal tissue was insufficient to stand the strain.

CASE IV

H. A. C., aged 52, male, underwent an operation for a right-sided renal calculus in 1920. The surgeon who performed the operation subsequently informed me that a prolonged search had had to be made for the calculi, and the convexity of the kidney was lifted up from pole to pole. The stone, a small one, was ultimately recovered. In 1926 he developed attacks of acute left-sided renal colic with haematuria, and x rays showed a shadow in the left kidney area.

Seen by me in October, 1928, his phenolsulphonephthalein excretion was 55 per cent., while his blood urea was 33 mg. per 100 c.cm.—an indication of a good total renal function. Cystoscopy showed frequent jets of urine coming from the left ureteric orifice. No urine was observed coming from the right ureteric orifice. Ureteric catheterization enabled normal urine to be withdrawn from the left kidney with a 10 per cent. phenolsulphonephthalein excretion in fifteen minutes, an indication of an exceptionally good renal function. No urine was obtained from the right-sided ureter catheter, and a subsequent investigation showed that the catheter lumen was patent. Double pyelography (Fig. 7) showed a normal left-sided pyelogram. On the right side the ureter and a rudimentary pelvis were shown distended with the solution of sodium iodide, but the calyces had vanished.

It is fair to assume therefore that the right kidney was so much damaged at the nephrolithotomy that it had become functionless. It is also fair to assume that had the method of x raying the exposed right kidney at the time of the 1920 operation been available the small stone would have been detected before the organ was opened, resulting in only localized damage instead of the kidney being rendered completely functionless.

The operations in Cases I, II, and III were performed in a private hospital. The pyelogram of Case IV was made in the same establishment, but on a separate, more powerful x ray plant.

CONCLUSIONS

1. Radiography of an exposed kidney is a method which has come to stay. It is helpful in guarding against the recurrence of a stone.

2. Detection of the exact site of a renal calculus by radiography is invaluable in preventing the needless sacrifice of renal tissue.

3. Illustrative cases are given: (1) of a previously known renal calculus; (2) of an occasion when a uric acid stone was suspected but whose presence could not be proved prior to radiography of the exposed kidney; (3) of a man in whom, after supposed removal of all the calculi, a remaining one was detected by radiography and removed; (4) of a sequel to a nephrolithotomy performed eight years before, the result being a functionless kidney owing to the extensive trauma at that operation.

THE TREATMENT OF PARANASAL SUPPURATION PERSISTING AFTER OPERATION

BY

A. J. M. WRIGHT, F.R.C.S.

SURGEON NOSE AND THROAT DEPARTMENT, ROYAL GENERAL HOSPITAL.

When I agreed to take part in opening this discussion I did so realizing that I had nothing original to offer and that I could therefore only give the results of my personal experience and perhaps to some extent emphasize what seemed to me to be the fundamental problems to be solved. I find that it is necessary to define the meaning of the subject chosen. We must presume that such operative intervention as has been carried out has been skilfully and adequately performed. The decision as to the adequacy of operation in such cases is in itself a difficult one. In considering this I take it that ventilation and drainage of the affected sinuses are the essentials. In addition in the case of the frontal sinus and possibly also of the antrum whose lining has been removed complete obliteration may be produced. While ventilation and drainage will cure the majority of cases it will not cure all and obliteration has only a limited application. Confining then the scope of our discussion to cases in which further operation is not advised, I suggest a classification into two groups: (*a*) those in which there is some discoverable factor which is perpetuating the suppuration and (*b*) those in which such a factor cannot be identified.

Dealing first with Group (*a*) I feel that this class merits some consideration as I find that it contains an appreciable number of cases seen by myself. The undiagnosed factors of which I have had experience have been the existence of a syphilitic or tuberculous infection, the existence of malignant disease, and the presence of a foreign body or of a bony sequestrum. The presence of an old standing syphilitic infection is not very uncommon and its recognition and treatment may be all that is necessary to clear up a case.

Tuberculosis is in my experience very much less common but its occasional occurrence is exemplified by the following case which has recently come under my observation.

The patient a woman aged 52 had had recurrent intranasal and external operations on the paranasal sinuses of both sides over a period of fifteen years without any relief. In addition to multiple operations her frontal sinuses had been washed out over long periods and the antra for twenty-five years. I found the nasal passages full of pus and crusts. The nasal mucosa presented a granulomatous appearance and on section showed the typical histological picture of tuberculosis. In early life she had had tuberculous glands removed from either side of the neck, and this might have afforded a clue to the nature of the infection.

The occurrence of malignant disease as a sequel to sinus suppuration is not I believe very unusual. This combination tends to delay diagnosis, the previous existence of suppuration distracting the observer's mind from the malignant factor. I can exemplify this by the case of a woman aged 46 who had worn an antro-alveolar plug attached to a dental plate for ten years, syringing pus out of the antrum daily. She consulted me owing to aching and a slight swelling in the cheek on the affected side, when I had treated her for a period as a case of simple chronic suppuration the existence of a squamous-celled carcinoma involving the anterior wall of the antrum became evident.

The type of foreign body most frequently met with is probably a tooth fragment in the antrum. I can best illustrate this occurrence by relating the following case which has already been published[1]:

A man, aged 24, had been complaining for eight years of a right-sided frontal headache and offensive nasal discharge. Examination revealed a chronic suppuration in all the anterior group of sinuses on the right side. Intranasal, and later external operations were performed without relief, but the suppuration cleared up rapidly following the spontaneous expulsion from the right side of the nose of a concretion, with a tooth fragment as a nucleus. This fragment had been present in the antrum since the extraction of a molar tooth at least ten years previously. After expulsion of the concretion, which had evidently passed out of the antrum into the nose through the opening made at operation, a further and more careful

[1] Read in opening a discussion in the Section of Laryngology and Otology at the Annual Meeting of the British Medical Association, Winnipeg, 1920.

examination of the original skiagram demonstrated its presence in the antrum

As to a sequestrum, we are probably familiar with cases, particularly of chronic antral suppuration, in which resolution is delayed after operation until the extraction or spontaneous expulsion of a fragment of dead bone

The treatment of the cases in Group (*b*) is, I understand, the primary object of this discussion We have to consider their treatment from two points of view—namely, local and constitutional Possible methods of local treatment seem to be repeated washing out of the sinus or sinuses, the use of suction to empty them, the application of antiseptic packs to prevent drying and to increase secretion, the use of oily applications for the same purpose, the employment of ionization with the idea of attacking the infection in the mucosa, and perhaps the use of radium

Experience has led me to believe that washing out should be avoided as far as possible in both the immediate and late post operative stages It seems to me to introduce a risk of spreading infection both to previously uninvolved regions of the nose and throat and to the ears without producing any favourable effect on the condition for which it is used I am of the opinion that the secretion should be got rid of by hawking or blowing and that an attempt should be made to keep an oily film over the surface of the mucosa to prevent drying and crusting I have had no encouraging results from the use of antiseptic packs with silver preparations, etc, but my experience with them is not extensive The technical difficulties in employing ionization in the paranasal sinuses are considerable, I have had no personal experience of the method, but, in view of the favourable results which have been obtained by its use in cases of infection of the mucosa of the middle ear, a thorough trial would seem to be worth while I have found that by using a relatively large dose of radium, only lightly screened, for a short time, an improvement is produced in cases of resistant ethmoidal infection with polypi A vigorous reaction occurs, and at the end of two or three months the local condition has been much improved I do not know if it has been employed for purely suppurative cases, if not, I should think a cautious trial would be justifiable

Treatment from the constitutional side is more difficult You have probably been struck by the great variation in the degree of general constitutional disturbance accompanying chronic sinus suppuration While some patients are more or less invalids, with muddy complexions and constant headaches, others, although their noses are constantly producing pus, are rosy-cheeked and never have a headache I have been impressed by the slight degree to which infection and new growth of the nasal sinuses involve the lymphatic system As long as infection remains within the nose, any evidence of involvement of the lymphatic glands is very unusual, while a spread to the skin, naso pharynx, or pharynx at once produces a lymphatic infection, as shown by enlargement of the glands I wonder whether this lack of absorption into the lymphatics may not be one reason why the body does not develop an adequate resistance to the infection If so, one would expect good results with vaccines Personally, I have found them of little if any use in chronic cases Anything which improves the general condition of the patient may be expected to have a favourable influence on the sinus suppuration, although, as I have already said constitutional and local improvement do not by any means always go together

There is one factor which I believe to be of the utmost importance and one which is frequently neglected—namely, time I have lived long enough to have seen cases which I regarded as incurable clear up with the passage of years, and I strongly advise that a very ample margin of time should be allowed to elapse after operation in these cases before judging of the result and particularly before deciding on any further operative treatment Many a patient has become a mental wreck through repeated operations which have not even improved the nasal condition In my opinion, provided reasonable drainage exists from the nasal sinuses, [illegible] if present are due to a general neurasthenia rather than to the secretion of pus in the nose Repeated operations do not relieve such cases but merely make them worse

AVERTIN.*

BY

F B PARSONS, M D, M R C P,

CAMBRIDGE

THE production of general anaesthesia is almost invariably effected by the inhalation of volatile substances This method has attained popularity for two reasons first, on account of the wide therapeutic margin of the volatile drugs available, and secondly, on account of the facility of administration which permits the anaesthetist to control and regulate accurately the depth and duration of anaesthesia Furthermore, absorption by this method is almost as rapid as by intravenous injection

Non-volatile anaesthetics must be given either by the mouth, the rectum, or intravenously, the choice of method being governed by the properties of the individual anaesthetic There are three groups (1) liquids with too high a boiling point for administration by the lungs, paraldehyde being an example of this group, (2) alkaloids such as morphine and hyoscine, and (3) solid substances, often very insoluble in water, which act by virtue of lipoid solubility This last group includes chloral and its derivatives chloretone, chloralose, and isopral, sulphonal and methyl sulphonal, veronal with its derivatives sodium veronal, luminal, and pernocton, and urethane with its derivative hedonal

All these drugs are excellent hypnotics, but as a general rule they are unsuitable as anaesthetics because the therapeutic margin is insufficient A dose that will produce insensibility and render the patient free from pain does not necessarily produce a corresponding degree of immobility, in some instances the anaesthesia lasts so long that the use of the drug is impracticable Unless a non-volatile anaesthetic can be administered by continuous intravenous infusion it must be given in a single dose, usually per rectum, and this has the disadvantage that when it has been absorbed it is impossible to control its action further In addition, there is always the risk of local irritation upon the rectal mucosa Such non-volatile drugs cannot be excreted rapidly, if at all, by the lungs, they are eliminated comparatively slowly by the urine, sweat, or faeces For these reasons it is impossible to ensure a constant concentration of the anaesthetic in the blood and tissues, a condition easily attained when volatile anaesthetics are employed, with this group, therefore, it is impossible to maintain the patient at a constant level of anaesthesia without the risk of overdosage The quantity to be administered must be calculated in proportion to the body weight of the patient, this method is the best at our disposal, and yet it is unscientific, because it takes no account of his age, temperament, or infirmity Further, if we accept the view that anaesthetics act by virtue of lipoid solubility, the obesity of the patient must be taken into consideration when estimating the correct dose There is no need for accurate dosage with a volatile anaesthetic, because there is a close correlation between the amount administered and the depth of anaesthesia With such difficulties to overcome the introduction of a new non-volatile anaesthetic may appear unnecessary, but it must be remembered that even volatile anaesthetics do not give entire satisfaction If the ideal anaesthetic is considered as one which is absolutely safe for the patient, produces complete insensibility and immobility, and is simple in administration the defects of the volatile type are at once apparent, and therefore the properties of any new anaesthetic should be critically examined

Avertin, or tribromethylalcohol, is one of the latest non-volatile anaesthetics, it was first prepared by Willstatter and Duisberg[25] in 1926 by the reduction of bromal It is an odourless white crystalline powder containing 85 per cent of bromine, and soluble in water to the extent of 3 per cent at 37° C, but the powder dissolves very slowly, taking more than forty-five minutes, though aided by vigorous shaking to produce a clear solution This was a serious disadvantage, but the drug is now issued already dissolved in amylene hydrate in the proportion of 1 grain

* A paper read in the Section of Anaesthesia at the Annual Meeting of the British Medical Association at Winnipeg, 1930.

of avertin in 1 c.cm. of the solvent. This solution is readily soluble in water; moreover it prevents the additional anaesthetic effect of amylene hydrate which also stimulates the respiratory centre and tends to counteract the depressant action of avertin upon respiration. The drug is given in aqueous solution by the rectum; it is peculiarly suited to this form of administration because it is non-irritating to the mucosa and it is absorbed therefrom within a very short time. Further, the therapeutic margin is greater when the drug is given in this manner.[12] Anaesthesia can also be produced by intravenous, subcutaneous or oral administration, but although these methods have been used for animals they are not so convenient for man.

Solutions of avertin must be freshly prepared without the use of heat; heating above 40° C. and exposure to light and air cause decomposition of the drug into dibromacetaldehyde and hydrobromic acid. Both these substances are intensely irritant to the rectal mucosa, and many of the earlier difficulties in the use of avertin by rectal administration were due to their presence. If a solution of avertin is decomposed by heat and injected into a cat's rectum an acute haemorrhagic proctitis results in a very short time. It is therefore important to be quite sure that a stable solution is being used, and before administration it must be tested for its reaction by adding two drops of a 1 in 1,000 solution of Congo-red to 5 c.cm. of avertin solution. If the reaction is less than $pH = 4.5$ (due to the presence of hydrobromic acid) the indicator gives a purplish or blue colour and the solution must not be used; but if the orange-red colour of the Congo-red is unchanged the solution is satisfactory. A 3 per cent. solution of avertin is commonly employed, because the required quantity of the drug can then be given in the smallest possible volume; it is probably better, however, to administer a 2.5 per cent. solution, because in this concentration the drug is more evenly absorbed by the rectal mucosa.[11]

Dosage

Correct dosage is a matter of considerable importance, for avertin is no exception to the general rule that when once an anaesthetic is given by the rectum it is impossible to control its action. No variation in the degree of narcosis can be effected by withdrawing any free avertin from the rectum, for the drug is absorbed completely by the time surgical anaesthesia is reached. When avertin was first introduced doses of 0.15 gram and over per kilogram of body weight were commonly used in the mistaken belief that full surgical anaesthesia could be obtained with safety. It has since been realized that this dose is unsafe for general use, 0.1 gram per kilo is safer and, for general purposes, more satisfactory because, although it produces complete anaesthesia in only 30 per cent. of cases,[5] the other 70 per cent. are in such a state of narcosis that a very little additional volatile anaesthetic serves to produce complete anaesthesia. This dose may now be taken as the standard for healthy patients, but for cachectic and exhausted patients, whose glycogen reserves are diminished and whose powers of detoxicating avertin are impaired, it is sufficient to administer 0.08 gram per kilo.

Although the smaller doses now given may be relied upon to produce deep narcosis they do not always produce full surgical anaesthesia. This may be achieved in one of two different ways: either by supplementing avertin by an inhalation anaesthetic, such as nitrous oxide or ether, or by utilizing Butzengeiger's method of giving small additional doses of the drug per rectum (for example, 0.025 gram per kilo) at fifteen minute intervals.[5] This intermittent method is not generally used probably on account of the trouble and time required and the grave danger of administering an overdose. Avertin should therefore be regarded as a particular form of premedication which will produce deep narcosis upon which full surgical anaesthesia can be superimposed by other methods.

It is generally agreed that 10 grams should be the maximum quantity of avertin administered to each individual irrespective of weight, though in certain cases the usual dose may safely be exceeded. The most important of these is exophthalmic goitre, where doses of 0.2 gram per kilo and even more can be given without ill effect; in tetanus it can be given in still larger doses when it reduces the number and severity of the spasms without unduly depressing the respiration. A case of tetanus has been reported[17] in which a total of 63.8 grams was given during a period of twelve days to a child weighing 20 kilos; this represents an average daily dose of 0.28 gram per kilo.

Many drugs have been employed as adjuvants previous to the administration of avertin in the attempt to produce full surgical anaesthesia. Veronal and its derivatives, morphine, and hyoscine have all been used extensively in this connexion. If morphine is first injected smaller quantities of avertin than would otherwise be necessary are required, but it has the grave disadvantage of accentuating the depressant action of avertin upon the respiratory centre. It is therefore inadvisable to use morphine as a premedicament unless the dose is restricted to 1/8 grain.

THE ANAESTHESIA

The induction of anaesthesia by means of avertin is most pleasant for the patient and easy for the anaesthetist. The pressure of the mask upon the face and the odour of the anaesthetic are abolished while the administration of an appropriate quantity of the warmed solution is associated with no inconvenience to the patient. The solution, which has been prepared and tested by Congo-red, is slowly run by gravity through a rubber catheter into the rectum. No obvious change occurs in the patient for ten or fifteen minutes after the administration is completed, after this interval he begins to feel drowsy, and gradually lapses into unconsciousness. There is usually no preliminary excitement or struggling. The respiration becomes slow and shallow, and a slight degree of cyanosis may be noticed. Anaesthesia deepens, and the operation may commence about half an hour after the administration was started.

At this stage it is necessary to consider whether an additional anaesthetic is required or not. The usual signs of anaesthesia are unreliable for, although the corneal reflex may be absent, a painful stimulus may elicit reflex movement and indicate that anaesthesia is not complete. According to Blomfield and Shipway[4] the best test is to apply a mask well wetted with ether to the face; if the breathing remains quiet the operation can begin, but if there is any holding of the breath full surgical anaesthesia has not been obtained and it is necessary to continue with ether or some other anaesthetic. In any circumstances a much smaller quantity of inhalation anaesthetic will be used than otherwise would be the case.

The blood pressure in man falls 10 to 20 mm. Hg and a comparable fall occurs in both cats and rabbits. Bender states[1] that this is due to loss of vasomotor tone, but my own experiment[18] indicate that it is due to a central cardiac effect and not to dilatation of the peripheral blood vessels. Avertin has a definite action upon the heart; it causes a slight increase, followed immediately by an appreciable diminution in the force of the beat which is accompanied by a slowing of the rate. In the isolated rabbit's heart this effect is marked when it is perfused with a 1 in 2,500 solution. Continuous perfusion with a strength of 1 in 1,250 causes arrest of the heart in systole within five minutes, an effect which is produced by chloroform in a dilution of 1 in 20,000. It appears therefore that so far as its action upon the cardiac musculature is concerned, avertin is about sixteen times safer than chloroform.

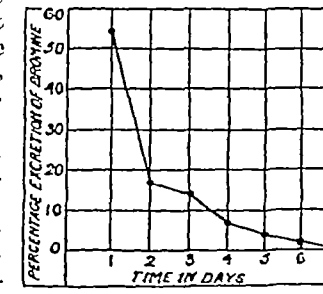
Respiration is markedly affected, it is very shallow and the rate may fall to 8 or 10 per minute. After the administration of a normal dose the centre still retains all its reflex effects and its response to drugs; in man the administration of ether by inhalation produces quickening of the respiration, while in animals inhalation of ammonia and the injection of hydrocyanic acid still produce quickening and deepening of respiration while the stimulation of an afferent nerve, such as the vagus or sciatic, elicits the normal response. If, however, the limits of safe dosage have been exceeded the respiration, in animals, shows that type of breathing known as apnoeusis. The animal first takes a normal inspiration which is followed, not by a normal expiration, but by five or six extremely

short expirations and inspirations, a normal expiration then occurs, and the process is repeated Toxic doses of avertin cause death from respiratory failure, and it is important, therefore, to keep respiratory stimulants at hand when administering this drug

The anaesthesia is very satisfactory for the surgeon, because muscular relaxation is complete, and it is comparable with that observed in chloroform anaesthesia The pupil in both man and animals occupies the midway position, but with toxic doses it is contracted A cat dies with pin-point pupils, and this affords a strong contrast with the dilated pupils which result from the administration of toxic doses of other anaesthetics This is due to a central effect, for there is no action upon the pupil when an aqueous solution of avertin is instilled into the conjunctival sac

With a dose of 0·1 gram per kilo anaesthesia is said to persist for about one and a half hours,[21] the patient subsequently passes into a deep sleep, from which he can be roused with difficulty, and which lasts for some hours There are usually no undesirable after-effects, and vomiting or nausea seldom occurs Avertin acts as an analgesic after operation, it is therefore of considerable value in diminishing post-operative pain and in abolishing the use of morphine for this purpose Further, the patient has no recollection of being anaesthetized, because avertin causes amnesia

The Fate of Avertin



It has been shown by Straub[22] that avertin is absorbed by the rectal mucosa quicker than the water in which it is dissolved, accordingly, anaesthesia is produced with great rapidity The subsequent course of events is uncertain, but it is stated[13] that the drug is detoxicated in the liver by combination with glycuronic acid It has been observed[10] that the duration of narcosis is longer in fasting animals on account of the diminished glycogen reserves, and this explains why a smaller dose of avertin is efficient for cachectic patients The converse, however, is not true, for the administration of glycuronic acid, glycogen, or cane sugar to a patient under avertin has no effect upon the duration of anaesthesia,[20] and consequently these substances are of no value for detoxication

There is no doubt that avertin is excreted by the kidneys, a sufficient quantity of bromine can be recovered from the urine to account for 98 per cent of the ingested avertin [7 18] Traces of bromine, however, can be found in the sweat and breath [23] The drug is not excreted unchanged, or as inorganic bromide for neither of these substances can be demonstrated in the urine The constant presence of glycuronic acid in the urine suggests that avertin is excreted as inobromalic acid—a compound formed by the union of tribromethylalcohol with glycuronic acid—but tests for this substance fail to prove its presence The assumption, therefore, is that the drug is excreted as a complex organic compound of bromine

At one time it was thought that avertin circulated in the blood stream as sodium bromide and was excreted as such [7] The suggestion was therefore made that the rectal administration of a solution of sodium chloride to a subject anæsthetized with avertin would diminish the period of unconsciousness and lead to a more rapid recovery from anaesthesia This depends upon the fact that bromides are excreted in the urine *pari passu* with chlorides, and if the rate of excretion of chloride is raised that of bromide will follow It would be easy, therefore, if the drug circulated as inorganic bromide, to bring an anaesthetized patient to consciousness as required a matter of considerable importance in view of the long period of narcosis following the injection It is now certain that avertin does not circulate as sodium bromide and hence the subsequent administration of sodium chloride has no effect upon either the duration of anaesthesia or the rate of excretion of bromine [18]

The concurrent administration of certain inorganic salts with avertin however has an effect upon the anaesthesia, as has been shown by Magnus and Magnus-Levy [24] when calcium or magnesium salts are given with the drug less is required Again, it has been shown [25] that the withdrawal of calcium and sodium salts from the body has a similar action

It has been suggested that certain other drugs are useful in detoxicating avertin, and both thyroxine[19] and caffeine sodium benzoate[6] have been used for this purpose Probably the former is the more encouraging, because patients suffering from exophthalmic goitre bear avertin anaesthesia extremely well, and can safely take far greater doses of the drug than can be tolerated by the normal individual Carlton suggests that the bromine in avertin saturates the thyroxine [6] Caffeine sodium benzoate, also, has been found to interrupt avertin anaesthesia in animals, and to stimulate respiration when this function is profoundly depressed, but personally I regard this suggestion with some misgiving, because it is now well known that the administration of caffeine in alcoholic and other forms of coma accentuates the toxic effect

Graph showing the rate of excretion of bromine in a rabbit weighing 1.8 kilograms after the subcutaneous administration of 0·4 gram of avertin (=0·346 gram bromine)

Avertin is excreted at a comparatively slow rate, experiments show that between 50 and 70 per cent is excreted in the first twenty-four hours following administration [18] Bromine is found in the urine in progressively diminishing quantities until about the seventh day (see chart), and therefore, since the drug is cumulative, great care should be observed in administering a second dose In spite of this, several instances[11 14 17] have been recorded in which large doses of avertin were given on successive days without ill effects to patients suffering from tetanus

The Present Position of Avertin

All rectal anaesthetics possess definite advantages over inhalation anaesthetics because, as already pointed out, the administration is more agreeable to the patient and simpler for the anaesthetist Avertin is preferable to other rectal anaesthetics because it does not irritate the mucosa, and it is unnecessary to wash out the rectum before administration or after the operation The preparation of solutions of avertin for injection is not difficult if the solution in amylene hydrate is used, but it requires some care Preparation, testing and administration should be carried out by the anaesthetist and not delegated to a nurse

Induction is most pleasant for the patient because there is no excitement or struggling, and the only sensation appreciated is that of falling asleep The anaesthesia is characterized by excellent muscular relaxation, which, for abdominal surgery, is accentuated by slow and shallow respiration The usual undesirable post-anaesthetic effects seldom occur, but, on the other hand, the patient requires constant attention on account of the prolonged coma

Serious drawbacks to the use of avertin as a routine anaesthetic are those concerned with detoxication and elimination From a study of the literature Lundy[15] has calculated that the death rate intrinsic to avertin, after making all allowances for the submission of bad risks to operation, is about 1 in 3,333 Hewitt's figures,[9] published nearly forty years ago, for the intrinsic death rates of chloroform and ether are 1 in 3,162 and 1 in 16,302 respectively Accordingly both avertin and chloroform anaesthesia have a similar risk to life which is much greater than that due to ether, it is evident that avertin is not an anaesthetic for general use when others at our disposal are much safer

Unlike chloroform, avertin has little effect upon the heart, its danger depends upon the fact that it is so slowly destroyed and eliminated It should therefore not be used when there is disease of the liver or kidneys, which hampers these processes As avertin produces marked respiratory depression its use is inadvisable when there is extensive disease of the lungs, nor can it, of course, be given when local disease of the rectum or colon prevents satisfactory administration

There are certain conditions, however, in which avertin has a definite advantage over other anaesthetics, and the

most important of these is exophthalmic goitre In this disease anæsthesia can be produced with the least possible distress and the excess of thyroxine present detoxicates the drug and minimizes the risk of toxic symptoms, the absence of any deleterious effect upon the heart is an additional advantage Avertin is of value in operations about the nose and throat when the use of inhalation anæsthetics is inadmissible, in spite of prolonged coma and depression of respiration it is stated[3] that it can be used in these cases without anxiety Further, it is useful in certain abdominal conditions because of the absence of post-operative sickness

It is possible that some persons are unduly sensitive to avertin, for even when allowances have been made for the unsatisfactory method of calculation, administration of the usual dose of 0 1 gram per kilo does not necessarily produce the same degree of narcosis in different subjects, for example, in some cases unconsciousness is not obtained, while in others death has occurred for no apparent reason[15 16] This is a point which might well be investigated further

My object in this paper is to indicate the relative advantages and disadvantages of oleid as opposed to volatile anæsthetics Avertin is perhaps the best of the solid anæsthetics which have been made available up to the present time, and although it is not so satisfactory for routine use as the volatile inhalation anæsthetics commonly employed, it is of particular service in the conditions which I have mentioned

CONGENITAL RADIO-ULNAR SYNOSTOSIS

BY

DAVID J DAVIES, M B, B S LOND, M R C S

ASSISTANT SURGEON TO THE PRESTON ROYAL INFIRMARY

CONGENITAL radio-ulnar synostosis which consists in ankylosis of the upper end of the radius and ulna, is exceedingly rare The condition is said to be due to a constitutional error—the result of the imperfect separation by the mesenchymatous tissue of the cartilaginous axials of the forearm, which take part in the formation of the bones

The factor which controls the development of a synostosis is unknown and various causes have been invoked to account for the condition Certain records suggest an inherited condition with synostosis as a dominant Mendelian characteristic a second possible factor is related to those which control the chondrification and ossification of the skeleton, many of the affected individuals being subject to exostoses In our case in spite of lengthy cross-examination of the patient and her relatives, we were unable to find a history of a tendency to loss of supination in any other member of the family whereas the patient was of healthy appearance and of normal stature, without any disproportion in the size of the limbs, etc , no exostoses were present

The condition is described as having three types (1) The radius is unaltered in shape but the head is ossified to the region of lesser sigmoid fossa of ulna (2) The upper part of the radius shaft shows no definitely moulded head (the headless type) and the upper end is moulded to the outer aspect of the ulna (3) In the "dislocated head" type the head of the radius is well developed, but it is displaced backwards or forwards This condition is usually unilateral, and associated with syndactilism, supernumerary thumb, or even absence of thumb The case here reported belongs to the third type, and it also presents the unusual occurrence of being bilateral

A girl aged 18 was referred to me on July 23rd 1929 at the out patient department and I reproduce the doctor's letter verbatim The bearer M S suffering from fractured left olecranon It was done seven weeks ago a stellate type of fracture was found The arm after extension was flexed to give her the carry to mouth and she was put on early massage Massage has not yet completely straightened the arm

On examination it was found that the left elbow could not be fully extended whereas flexion was normal The hand was held

FIG A.

FIG B

in semi pronation but no supination was possible Pronation could be carried out to about 90 degrees The olecranon process appeared to be deviated towards the medial side of the elbow whereas the head of the radius was directed towards the posterior aspect of the external condyle of the humerus and was palpable as a distinct projection on the outer side of the elbow No trace of the olecranon fracture of the elbow could be made out On examination of the right elbow it was found that a similar condition was present the arm being held in semi pronation with limitation of extension Flexion at the elbow-joint was normal whereas pronation could be carried out to about 90 degrees

The muscular development was normal and there were no exostoses present There was no disproportion between the upper

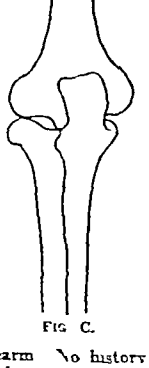

FIG C.

FIG D

arm and forearm No history could be obtained of any familial difficulty or abnormality The patient stated that she could not carry things as other girls could but she had not found any disability in doing her work The blow on the elbow had caused much pain when incurred and it was only after this that the mother thought that the patient could not extend the arm properly

X ray photographs were taken of the elbow joint radius ulna and humerus on both sides and line drawings have been made From these it is seen that the radius of the left side is more curved than normal (Fig A) The head of the radius is somewhat expanded and displaced backwards with relation to the humerus and does not articulate with the humerus A clear definition cannot be seen between the radius and ulna and ossification appears to be present between the radius and the ulnar region of the coronoid process A similar condition is seen in Figs. D and C which were taken of the right elbow region Fig A shows how it was possible in a bad radiogram to diagnose a fracture of the olecranon

The case presents certain interesting features
1 The rarity of the condition, especially of bilateral "dislocated head" type of synostosis With a view to determining whether any cases are accidentally missed 500 radiograms taken at the Royal Infirmary of elbow-joints were examined, I was unable to discover a case of synostosis
2 The importance of recognizing the condition in view of possible "compensation" for the loss of extension and supination, which the anxious parent may only discover for the first time after an accident
3 In spite of the definite deformity, the little inconvenience entailed, in this case the blow in the region of the elbow was the first idea that the girl's parents had of anything unusual The condition therefore does not require any surgical intervention
4 As regards causation, this case does not fall in with the theory of generalized defect of the controlling factor of chondrification and ossification, there were no other defects, such as exostoses
5 No hereditary influence could be ascertained
Since the foregoing was written another case of synostosis has been seen by me, but this case belongs to the first of the three types, and is unilateral

A child aged 4 years was brought to the Royal Infirmary on account of stiffness after knocking the elbow There was no sign of bruising and on examination it was found that extension and flexion at the elbow joint were normal Supination was not possible and pronation was only possible through an angle of 20 degrees There was no evidence of any dislocation and the bony points seemed to be in normal position The extensor ossis metacarpi pollicis and extensor brevis pollicis were somewhat taut The grip was unaffected, but the carrying of objects involved adduction of the elbow An *x* ray photograph was taken, a tracing of which is seen in Fig E There were no exostoses and no family history of a similar condition
The case was first seen in May, 1930, by Mr Chisholm, F R C S, and now (August, 1930), after massage and movement, the muscles referred to seem normal The child is able to carry out normal movements with greater ease than when seen in May

Here again we find certain important factors, which have been already discussed
1 The condition is first noticed after an injury

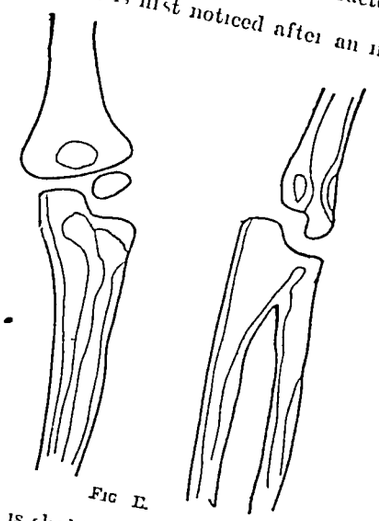

FIG E.

2 Inconvenience is slight
3 No hereditary influence could be ascertained
4 The signs do not accord with the theory of generalized defect of the controlling factors of chondrification and ossification, there was an absence of exostosis, as in the first case

I am indebted to Drs Rayner and Harrison for the use of the *x* ray films, and to Mr Chisholm, resident surgical officer to the Infirmary, for sending me the second case

AN OUTBREAK OF PUERPERAL FEVER IN A NURSING HOME

BY
J S MANSON, M D, D P H,
MEDICAL OFFICER OF HEALTH TO THE RUNCORN RURAL DISTRICT

THE present interest in maternal mortality affords an excuse for the narration of the following observations and facts in connexion with an outbreak of sore throat, puerperal infection and scarlet fever in a nursing home The house was formerly a private residence standing in its own grounds It is drained to a sewer, and is in every way hygienic There are eleven rooms, seven of which accommodate patients The staff consists of the proprietor who is a fully trained nurse with the C M B, and another fully trained nurse When there are sufficient patients work in a former home conducted by her, where she had upwards of 300 cases without a death and without a trouble to cause anxiety In the present home she had 83 cases without incident until the first trouble arose in January, 1930

CASE I

A primipara aged 21 developed a sore throat and then a rash the day after a normal confinement There was a slight tear which was sutured Only one vaginal examination was made by the matron the doctor in attendance made none The patient was removed to hospital by the matron the doctor in attendance made none and the patient was removed to hospital where she received treatment for scarlet fever was diagnosed and the patient was removed to home in a neighbouring city where she received treatment for scarlet fever antitoxin at the hands of a gynaecologist at the hands of a gynaecologist The convalescence in which albuminuria appeared she

Following there were 8 normal cases, in one of which a sore throat developed but the patient said she had had a sore throat of a similar character This was attributed to the home when B was admitted twenty-two days after A had been removed

CASE II

B a primipara aged 23, had a normal confinement, breech presentation and had had one vaginal examination There was a perineal tear, which was sutured On the third day after the confinement she developed a sore throat temperature 101° F, and had a generalized patchy rash She was removed to hospital, where she died seven days after the confinement

There had been no contact between B and the aforementioned patient with slight sore throat The home was thoroughly disinfected and aired, and no new cases were admitted for a week The matron was advised to use gauze face-masks when in attendance on patients, and she and her assistants carried out this instruction Sixteen normal cases followed, and seventy-two days elapsed before C was admitted

CASE III

C was a primipara aged 30 Labour was instrumental, and there was a perineal tear, which was sutured Two days later this patient developed a temperature and a severe pain in the sacral region, which was attributed to rheumatism This pain was so intense especially on movement that the perineal toilet could not be carried out satisfactorily This pain was presumably secondary to a slowly developing streptococcal infection of the torn perineum The patient was three weeks in the home, and was seen twice by a gynaecologist She returned to her own home and then went to a private nursing home, where it was decided that she had had pelvic infection Recovery took place, but convalescence was prolonged

While this patient was in the home three others were admitted, and these had normal confinements and puerperia

CASE IV

D a primipara aged 23 was admitted on the day C left the home and had a normal confinement two days later Two vaginal examinations were made by the matron The doctor in attendance made none There was no perineal tear Three days later the patient developed a temperature and a severe sloughing vaginitis from streptococcal infection She was removed to hospital, where she died ten days after the confinement

CASE V

F a primipara aged 30 had a normal confinement one day after D's confinement a perineal tear was sutured On the seventh day after the confinement she developed a temperature of

101° F and a rapid pulse She was removed to hospital and recovered after prolonged convalescence

The only patient now in the home was sent to her own home and the place was closed to further admissions for a week and thoroughly disinfected and aired The throats of the matron and assistant nurse were examined but no evident signs of inflammation were present A swab from the throat of the assistant nurse was taken and the bacteriological report stated "Streptococci present—non haemolytic"

Three days after the removal of F the matron developed a sore throat, and three days later the well marked rash of scarlet fever She was removed to the isolation hospital, and the home was again disinfected and the restriction for admission of patients extended for another week

Discussion

How did the infection in these cases arise? None of the infected cases occurred in the same room, all were in different rooms which did not communicate directly with each other One doctor attended B and C but there was an interval of seventy-two days between, and this doctor had attended several cases in the interval without incident The other cases were all attended by different doctors The matron and nurse had attended 18 primiparae and 8 multiparae between A and F, and all had normal puerperia In view of these facts it would be difficult to assert that the antiseptic technique followed in the home was faulty, without discovering the fault in the cases that were infected, and this could not be done

The possibilities of infection from milk were considered, especially when the matron contracted scarlet fever There did not seem any possibility of her being infected from contact with an infected person She had only been out in her private car for two short runs in the fortnight previous to the onset of the disease The milk was supplied from a dairy in bottles, and was said to be pasteurized before delivery In spite of this the possibility of a milk infection in cases of puerperal fever with sore throat was kept in mind and the matron was advised to boil the milk supplied to future patients

While autogenous infection might explain the illness of A and P_2 it would be wholly erroneous to assume such infection in C D and E and in the matron, who was attacked by scarlet fever All these cases occurred within a month and were attacked one after another so must have been related to some common source of infection Did this infection enter the home by a visitor or was there a carrier among the other patients? It is impossible to say

THE BLOOD CALCIUM IN DIABETIC RETINITIS

BY

R D LAWRENCE, M.D., M.R.C.P.,*
KATE MADDERS, M.B., B.S.,
AND
H. R. MILLAR

(From the Biochemical Department, King's College Hospital)

In a recent publication Cammidge[1] reports that he has found a low calcium content of the blood in cases of diabetes with retinitis and has suggested that this calcium deficiency might be the cause of the retinitis He states that in 81 per cent of his retinitis cases the blood calcium figures were low enough to be considered distinctly pathological" It is a little difficult to gather what he considers abnormal figures, because few are mentioned in his publication In the one case recorded in any detail 5 mg. per cent is stated to be a 'subnormal value," and 6.5 mg. per cent "the maximum normal figure" Presumably these figures were obtained on whole blood in which the normal content is usually said to range from 5 to 7 mg. per cent It is more usual to estimate the serum calcium which varies from 9 to 11 mg. per cent, though some authors extend this normal variation from 8 to 12 mg. per cent

It seemed important to confirm this new observation on which a therapy might be based and the point has been investigated in known cases of diabetic retinitis attending our diabetic clinic no selection of cases was made but the first ten patients who happened to attend were taken and our results show that we have been unable to detect any abnormality in the serum calcium contents of these patients The tests were performed in duplicate by the Kramer and Tisdall method

Results

The average serum calcium of these ten cases was 9.6 mg. per cent, the lowest figure was 8.6 and the highest 11 mg. per cent Seven cases fell between 9 and 10.5 mg. per cent, and in no case therefore, was an abnormally low or high figure obtained Admittedly the number of cases investigated is small but the uniformly normal results make it clear that the blood calcium has no diagnostic or etiological importance in these cases

A few other facts of etiological importance in retinitis should be mentioned Five of the patients were males and five females The average age was 61 years the youngest being 44 and the oldest 71 Seven cases were severe enough to require insulin The minimum ascertainable duration of the diabetes was two years, the maximum twenty years Three patients showed traces of albuminuria without other evidence of Bright's disease, in them the retinal picture was that of diabetic retinitis alone Gross arterio-sclerosis was not a noticeable feature The mean systolic pressure was 150 mm. Hg the diastolic 90 mm. the highest systolic pressure was 185 mm. the lowest 100 It is clear, therefore, that true Bright's disease and hypertonic arterio-sclerosis were not important etiological factors in these cases, which appear to be really "diabetic" in nature

Summary

We are unable to confirm the observation that retinitis in diabetics is accompanied by a low blood calcium content, which we have found, indeed to be normal

MARKED HYPERGLYCAEMIA WITHOUT GLYCOSURIA

BY

GILBERT H. C. ST. GEORGE GRIFFITHS,
M.R.C.S., L.R.C.P.
ASSISTANT SURGEON, COLONIAL HOSPITAL, GIBRALTAR

SINCE some law down the cast-iron rule that each person has a definite "renal threshold," the occurrence of a case presenting at one time marked hyperglycaemia without glycosuria deserves to be recorded, if not because it is unique at any rate by reason of its rarity

A married woman aged 55 was admitted to the Colonial Hospital Gibraltar on March 26th suffering from a bad septic hand she was very sallow unhealthy and anaemic and there was marked pyorrhoea alveolaris with dental caries The heart was apparently normal the pulse rate varying from 84 to 99 per minute Pyrexia was slight or absent a surprising point in view of the extensive septic lesions in the left hand. The urine was found to be loaded with sugar and the diacetic reaction was positive The total quantity of urine was never excessive—at no time more than three pints—and the patient never suffered from undue thirst For treatment fomentations and eusol bath were given locally an iron and arsenic tonic was administered for the anaemia and a light diet consisting of bread-and-butter two Moorish eggs pudding beef tea and one pint of milk, was ordered temporarily The patient was so unhealthy and her general condition so bad, that it was considered too risky to place her on any strict diet without further examination and consideration

Besides the routine daily analysis of the urine in the ward a specimen was sent to the laboratory on March 28th when 26.3 grams of glucose per litre were recorded There was no reaction to acetone or diacetic acid On the following day the blood sugar and urine sugar estimations were repeated The blood sugar had advanced to 0.366 gram per litre while the urine contained slight amounts of acetone and diacetic acid

On March 30th an injection of 10 units of insulin was given tentatively and repeated the following morning one hour before

* Working on diabetes with the Medical Research Council.

her dinner. The dose was increased on April 1st to 12 units daily, and a course of colloidal manganese (0.5 c.cm.) was commenced on the next day for her septic condition. During this time the index finger of the left hand was incised under local anaesthesia, and the hand and fingers improved markedly, but two further abscesses started forming above the annular ligaments. The urine was being checked daily in the ward, always with a heavy fall of sugar. On April 4th the insulin dose was further increased to 15 units, and, since her general condition was so frail, an ounce of brandy was started on April 6th. An examination on the next day showed that the blood sugar figure was higher—0.427 per cent.—but the urine sugar figure had fallen to 2.1.7 grams per litre, the acetone reaction was marked, but only a small amount of diacetic acid was present. In view of this report it was decided to give her two daily injections of insulin, each of 15 units. Her general condition was most unsatisfactory. She was quiet and inclined to be drowsy, and there was appetexia and anorexia, she practically refused the original diet, and was really only taking milk, eggs, and beef tea. In the evening, as she was so drowsy, it was decided to administer further injections of insulin, 20 units at 9 p.m. and again at 1 a.m. On the morning of April 8th she was semi-comatose and extremely weak, the pulse was up to 100 per minute and the urine was still loaded with glucose. Insulin in 30-unit doses was administered four-hourly throughout the day and night, and sodium bicarbonate was also ordered. The blood sugar improved on the following morning to 0.356 per cent., and the urine contained no acetone or diacetic per litre while the urine contained no acetone or diacetic acid. Owing to the feebleness of the heart and pulse, alternate injections of digitalino and strychnine were given to sustain the circulation.

On the morning of April 9th insulin in doses of 30 units was administered at 10 a.m. and 2 p.m., and later repeated four-hourly throughout the night. The patient became mentally clear and less drowsy. The pulse remained rapid at 120 per minute, in spite of cardiac stimulants. On April 10th the blood sugar figure was highly satisfactory (0.184 per cent.), there were only traces of sugar in the urine, which was entirely free from acetone and diacetic acid. The insulin dosage was reduced to 20 units every four or six hours. Signs of threatening hypo-glycaemia were noted following the insulin injections, and an orange was ordered to ward off these symptoms.

On April 11th the patient's general condition was very grave, owing to the debility and exhaustion. She was mentally clear and not drowsy; the pulse was still rapid (120 per minute) but it was stronger and more regular. The blood sugar figure was estimated twice at 11 a.m. it was 0.48 per cent., but at 1 p.m. it rose to 0.633 per cent. no more than a trace of urine sugar was present. There was nothing to account for this huge sudden increase in the blood sugar. Insulin injections (20 units four-hourly) were resumed, and on the following day the satisfactory blood sugar figure of 0.162 per cent. was recorded, and a trace of glucose only in the urine. The patient's general condition was unsatisfactory, however, and she was obviously dying from exhaustion and debility. On whatever spot of her body she rested a bruise appeared, with or without septic pressure sores, and eventually she died at 6.30 a.m. on April 13th. At no time was acetone noted in her breath.

The point of special interest in her case was the marked hyperglycaemia occurring on April 11th. As will have been noticed the blood sugar content was twice estimated for fear of error, at the first time it was 0.48 per cent., while on the second occasion, at 1 p.m., it had risen to 0.633 per cent., glucose was absent from the urine, or only present as a slight trace. Her "renal threshold," after studying the figures of her case, appeared to be somewhere near 0.18 per cent.

The problem arises, Why did such a marked hyperglycaemia develop twice on April 11th, with, at the most, only a trace of glucose in the urine? Why was there no corresponding increase of glucose in the urine? There was the possibility of error in the laboratory. I investigated this point and discovered that the standard solutions for blood sugar estimations had been used, that they were not diluted that no error of multiplication could arise, and finally that the same solution had been checked on a normal blood sugar case the same day. The ward tests for sugar in the urine confirmed the absence of it, thus excluding the possibility of human error in the laboratory. The extraordinary condition of marked hyperglycaemia occurring temporarily without glycosuria was recorded in a patient who before and after April 11th reacted normally to insulin, and appeared to have a very definite "leaking point" at about 0.18 per cent. The question arises whether such a contradictory state is possible, and, if so, what could have been the cause, unless it was sepsis, with the corresponding toxins.

A NEW PASTE BANDAGE FOR THE TREATMENT OF VARICOSE ULCERATION AND PHLEBITIS

BY

C. J. CELLAN-JONES, M.D., F.R.C.S.Ed.,
ASSISTANT SURGEON, SWANSEA GENERAL HOSPITAL,

AND

KATHERINE M. CELLAN-JONES, M.D., D.P.H., B.Hy.,
ASSISTANT MEDICAL OFFICER OF HEALTH, SUNDERLAND

(With Special Plate.)

It is a reluctant general admission among those who have interested themselves for a sufficient period in the healing of varicose ulceration that the ideal method of treatment in this treacherous and stubborn condition is prolonged rest in bed with elevation of the affected limb. This is the only completely satisfactory way of eliminating circulatory stagnation from a varicose superficial venous system, or of draining a massive oedema which results from profound venous thrombosis. The ulcer so treated gradually becomes analogous to a healthy wound on any other part of the body, and healing is then rapidly accomplished.

So seldom, however, is this Utopian arrangement possible that numerous ambulatory methods of treatment have been evolved, each contributing to the degree of its success by the efficacy of the same basic factor—that of applying a firm mechanical support which is designed to compress the varices and to prevent the accumulation of fluid in the tissues. These methods may be broadly classified under the following headings: (1) crepe bandages, (2) woven elastic hosiery of all varieties, (3) rubber bandages, (4) strips of adhesive plaster applied in numerous ways, (5) cloth or chamois leather gaiters, (6) closely fitting Plaster-of-Paris bandages (still adhered to by some heroic practitioners), and (7) Unna's paste dressings. It is not our intention to offer a general criticism of these various measures, or to discuss their individual efficiency, costliness, or difficulty of application.

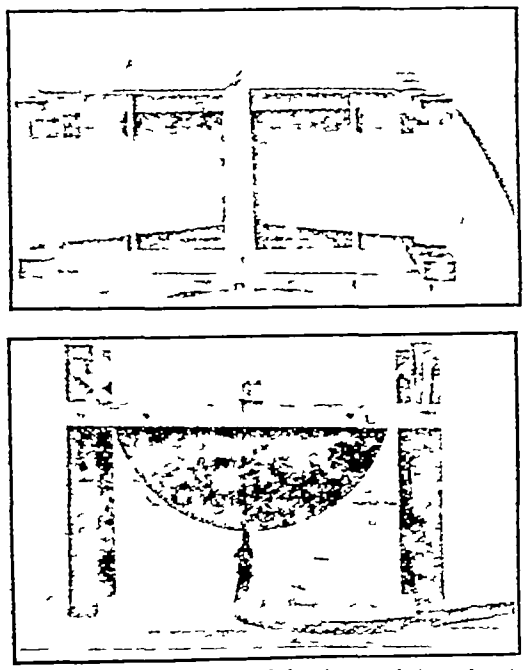
Until three years ago we confined our experiments in the treatment of ulcers and phlebitis to the original zinc gelatin paste of Unna, and to the numerous modifications of this formula which have since been introduced. The following tabulated group, in which the figures throughout represent parts by weight, will serve to indicate the diversity of opinion as to the ideal paste:

Varieties of Unna's Paste	Zinc Oxide	Glycerin	Water	Gelatin	Starch	Gum Arabic
The original	10	15	40	20	—	—
Thomas	10	20	20	10	—	—
The soft (Gougerot)	10	17	30	10	—	—
The hard	10	30	30	30	—	—
Saint-Louis ,,	10	30	30	25	—	—
Héis ,,	10	40	40	10	—	0.5
Leroy ,,	10	25	45	12.5	—	—
Segard ,,	10	20	40	40	—	—
Brandon ,,	10	16	22	10	—	—
Gilson (Manchester)	10	12	22	6	—	—
Smith (Glasgow)	10	10	10	10	—	—
Clasen	10	40	30	20	—	—

We are satisfied that the good results following the use of zinc-gelatin dressings are due to the following factors:

1. The medicaments are useful. Glycerin is dehydrating and hence antiphlogistic, it has a definite place in the reduction of oedema. Zinc oxide, again, is both antiseptic and astringent.

2. When applied on light dressing material the paste does not prohibit the evaporation of skin secretions and it allows air-access to the tissues. These advantages are not obtainable with rubber or elastic webbing bandages.



3. When properly applied the zinc-gelatin bandage forms a satisfactory mechanical support.

4 It is an inexpensive method of treatment and in the case of ulcers which are discharging profusely, the dressing can be much more readily discarded than the costly elastic webbing or crepe bandage

In spite of these four valuable features the use of Unna's paste has been cognizant of the definite disadvantages which it possesses as regards speed and tidiness of application Paste made up according to any of the formulae quoted is when cold a solid slab of jelly It has to be melted before use and must then be applied with a brush to the skin and subsequent layers of dressing Thus, when there are large numbers of cases to be treated, a great expenditure of time is required and however expert one becomes the melted paste almost inevitably splashes the patient's garments and everything in the vicinity

After experimenting for nearly two years we eventually compounded a formula which while retaining the useful medicaments of Unna's paste is capable of considerably simplifying the technique of applying supporting bandages This paste contains the following substances in parts by weight zinc oxide, 10 glycerin 10 sterilised refined glue 4 gum acacia 5, and water 30 When cold this is a viscous medium which becomes much more fluid on warming

A sufficient quantity is placed in the double-jacketed basin attached to the apparatus and warmed by hot water, which occupies the space between the jackets A bandage of requisite length and width is now wound on one roller of the machine and carried through the basin under a series of crossbars, to a second roller, where it is rewound after being thoroughly soaked in the warm paste (See illustrations) In this way a bandage which is impregnated with zinc oxide and possesses highly adhesive properties is produced The bandages are wrapped in grease proof paper and are stored ready for use in airtight tins They never solidify in the same way as would the ordinary zinc-gelatin, but remain soft, very sticky, and quite pliable even when kept for months No preparation is required before they are applied in the same fashion as ordinary cotton bandages

Special bandage machine used for the manufacture of paste bandages for the treatment of varicose ulcers Note external water jacket which renders the paste sufficiently fluid for ready use

Bandages of the type supplied to the requirements of the national health insurance authorities will be found unsatisfactory for this purpose They are so closely woven that their suppleness is sacrificed in the cause of strength moreover, it is most difficult to impregnate them completely with the paste In preparing some two hundred bandages weekly to meet the requirements of the Swansea Hospital clinic we use only the cheap three- and four-inch 'hospital" bandages which have not more than twenty-two strands of thread to the inch of bandage length and thirty-five strands to the inch of width

Method of Using the Prepared Bandages

The first measure in commencing the treatment of an ulcer which is discharging offensively is immersion in a hot eusol bath for a period of fifteen minutes The affected limb is now elevated and in this position all encrustations are removed from the edges of the ulcer and from the surrounding skin surface Much of the oedema can simultaneously be reduced by gentle stroking massage in the direction of the trunk Irrigation of the raw surface is carried out with a weak solution of hydrogen peroxide, followed by normal saline solution and the ulcer is then dressed with layers of gauze cut exactly to the size of the excavation and soaked in eusol The thickness of the gauze is just sufficient to reach the level of the surrounding skin and is covered by a thin layer of wool intended to absorb some of the copious discharge which always appears during the early stages of treatment

With the foot at right angles to the leg a strip of four-inch paste bandage is now placed with its centre over the point of the heel and its ends almost meeting in front of the ankle joint A second and a third strip are similarly applied, partly overlapping the first thus completing what might be termed a separate "heel-cap" A strip of bandage is now placed with its centre under the arch of the foot and its extremities at the level of the head of the fibula on the outer side, and at a corresponding point on the inner side This is the "stirrup" which greatly strengthens the entire bandage In cases where oedema is particularly massive longitudinal strips are also placed in front of and behind the leg in order to prevent the bandage from cutting into the leg between the turns Commencing at a spot just proximal to the toes the paste bandage is now completed by carrying a "figure of eight" up to the level of the head of the fibula The best results are obtained when these bandages are applied as tightly as the patient can reasonably endure them To prevent the sticky dressing from adhering to the stockings a roll of tissue paper or, failing this, an ordinary dry bandage, is now applied, it may be removed by the patient as soon as the paste has dried

Within a few hours of application the warmth of the limb dries the moisture from the bandage, the twists of which then become closely adherent to one another and moulded to the leg thus producing a firm though elastic support, which will remain efficient for three weeks to a month if desired The whole procedure must be carried out twice weekly at first, but longer periods are very soon allowable between the dressings, and in most instances only a short time has elapsed before weekly treatment is sufficient Even in the acute stages the secret of success is to change the applied medicament as soon as its healing effect fails to be sustained Ulcers, for example, which do not improve with eusol dressings, will often react very rapidly to a 0 1 per cent solution of acriflavine, or to an emulsion of this drug in paraffin Although ointments are not generally recommended, 'varul," an irradiated ergosterol ointment with added zinc oxide, frequently induces rapid healing in clean, chronic ulcers

The paste bandage interferes in no way with the injection treatment of veins, in fact, it provides relief in those cases where a smart reaction, accompanied by swelling and tenderness follows the injection of the various sclerosing media The only difference we make in these instances is to cover the injection sites with a thick pad of wool to prevent painful pressure

In phlebitis the treatment is particularly successful both in reducing oedema and in dispelling the tense inflammatory condition The entire hot and dusky area is well covered with pure ichthyol dressed with a thin layer of gauze and wool, and finally paste-bandaged in the ordinary way These cases need only be dressed once a week In the dry and irritating forms of varicose eczema we have found that the best results follow when the bandage is applied over strips of lint spread with an ointment containing 2 parts of crude coal tar, 4 parts of zinc oxide, and 16 parts of vaseline.

Comment

The paste bandage has now been in use for a period of three years, during which time it has successfully healed some hundreds of ulcers of a chronicity ranging from three months to fifteen years One of us has had the opportunity of gauging its efficiency in a large hospital clinic and in consulting practice, the other has tested it thoroughly in a charitable dispensary where assistance is distinctly restricted, and where patients during treatment are bound by circumstances to carry on their full daily work in a variety of laborious occupations

From the patient's point of view the paste bandage appears to be a very satisfactory application, the remark which most of them make after the initial dressing is that they have had their first night of sound sleep for some months, or that they already feel fit to recommence their employment While we have found that the paste bandage constitutes a definite improvement upon the methods so far available, both in convenience of application and in the results obtained, we do not pretend that it is a panacea for all varicose ulcers In some cases, for example, where the ulceration has existed for many years and is accompanied by massive oedema and deeply seated phlebitis, the ultimate prognosis remains somewhat gloomy The primary cause of the trouble cannot be eradicated, and even when healing occurs, unless the bandages are permanently worn, recurrences are more than likely to present themselves

The self-explanatory illustrations shown in the Plate are chosen from a series of photographs of ulcers before and after treatment

The thanks of the authors are due in a great measure to Miss R E Jones, chief pharmacist to the Swansea General Hospital for her assistance in compounding the formula for the paste bandage, and to Sister Golden of the Shooters Hill Hospital, London, for her invaluable help in elaborating the technique of ulcer treatment

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

HENOCH'S PURPURA IN AN ADULT

In the *British Medical Journal* of August 16th (p 249) Mr F W Widgery reports a case of Henoch's purpura in a man aged 23, and states that at first the diagnosis was doubtful on account of the patient's age It may be interesting, therefore, to place on record another case of what I believe was Henoch's purpura in an adult

On September 17th, 1929 I saw a grocer's assistant, aged 36, who complained of headache aching pains in his limbs, and general malaise He had a slight cough his temperature was 99° F and his pulse 80 There were no other physical signs Next day he had pain round the umbilicus, there was some tenderness in that region and in the right iliac fossa The stools were normal On September 20th there appeared a profuse petechial rash scattered over the trunk and limbs, it was purplo in colour the spots ranging in size from that of a pin's head to a split pea The abdominal pain was severe and the tenderness greater On September 21st the stools were frequent, loose, and black but there was no vomiting the abdomen was swollen and tympanitic On the next day the stools were still dark, but becoming lighter there were many more purpuric spots During all this period the temperature ranged from 99° to 100 5° F On September 22nd the stools were normal in colour, soft, but severe the diarrhoea had ceased There was still a good deal of abdominal pain and tenderness though it was less was fading there were no more fresh spots On October 9th the patient had improved generally but was still very weak and looked emaciated The temperature was 99°, and the pulse 80 He was slightly constipated the abdomen was distended, and he still complained of slight pain and tenderness in the umbilical and right iliac regions The spleen was not palpable The apex beat was in the fifth interspace the cardiac dullness had not increased, and there were no adventitious sounds The urine contained a slight haze of albumin An examination for *B typhosus* was negative

On October 11th a blood examination resulted as follows Red blood cells 4 900 000 per c mm white cells 14,000 per c mm, haemoglobin 100 per cent A differential count showed poly morphonuclears 88 per cent, large mononuclears 4 per cent, and lymphocytes 8 per cent On October 24th the faeces were reported negative for *B typhosus* Three days later he complained of pain in his right leg and thigh, and there was some oedema The urine was negative to *B typhosus* On October 29th the white corpuscles numbered 20,000 per c mm, the polymorphs 84 per cent, large mononuclears 12 per cent, and the lymphocytes 4 per cent From then onwards convalescence proceeded steadily but very slowly The oedema of the right leg persisted, and on August 5th, 1930 when he resumed work, was still in evidence in the evening of each day.

FRACTURE OF THE FRONTAL BONE INVOLVING THE FRONTAL SINUS, WITH FORMATION OF AN INTRACRANIAL PNEUMOCELE

(With Special Plate.)

The following account of a case, accompanied by radiographs, may be of some interest

The patient, a man between the ages of 20 and 30 met with a motor-cycle accident on April 25th, 1929, he was removed to a local hospital, and remained unconscious for four or five days On recovering consciousness he suffered considerably and intermittently from headaches In June 1929 he was discharged from the hospital, and on July 26th he was admitted to the Hospital for Epilepsy and Paralysis, Maida Vale suffering from headaches, intermittent weakness of left arm and left leg, and blurring of the vision of the right eye

A few days after admission x-ray photographs were taken of the patient's skull, and a comminuted fracture of the right half of the frontal bone, leading into the frontal sinus, with the formation of a large intracranial pneumocele, was discovered Following this an operation was performed under local anaesthesia, a small piece of the right half of the frontal bone was removed, a small tear in the dura mater found and sutured, and the channel which led into the frontal sinus plugged with wax At the finish of the operation, almost at once did the patient volunteer the statement that the headaches were better He was again x-rayed about four days later, and it will be noticed that the intracranial pneumocele has disappeared

Fig 1 is a lateral view taken with the head lying on the occiput This shows how the pneumocele has risen to the top, also the fracture leading into the frontal sinus A radiograph was taken with the head in the reverse position but the alteration to the pneumocele was not very marked owing to absence of any large quantity of cerebro spinal fluid Fig 2 was taken in the same position as Fig 1 It shows the appearances after operation

I desire to thank Dr D McAlpine for permission to use the clinical notes

Epilepsy and Paralysis

SECONDARY ABDOMINAL PREGNANCY

The following case presented interesting points in diagnosis and treatment

A married woman, aged 32 with three children, the youngest of whom is 5 years old, had been under prolonged treatment for pelvic inflammatory trouble, which originated with a vaginal discharge and painful micturition Her condition had gradually become worse, and pain in the right iliac fossa caused her to seek admission to hospital

On examination the signs and symptoms suggested pelvic cellulitis Vaginal examination revealed a tender mass occupying the pouch of Douglas, micturition and defaecation were painful On palpation the lower right rectus muscle was guarded, and deep pressure caused much pain Abscess formation was suspected General and local treatment was instituted, and two days later a brownish mucous discharge appeared from the vagina On close questioning it was found that this had also occurred on one or two previous occasions, otherwise the menstrual history was uninterrupted The pain continued, and shreds of decidual membrane were passed, the probability of ectopic gestation was considered, and a laparotomy was decided on

The abdomen was opened in the middle line, and a secondary gestation sac was found, which consisted of a mass of adhesions of the parietal peritoneum omentum, and intestine On separation of these a foetus of about four months' gestation was found and delivered The cord was traced downwards, and the placenta separated from its attachments in the pelvis The haemorrhage was profuse, but soon ceased on pressure with hot towels The large sac was drained, and for several days clots and fragments of membrane were discharged from the tube, and, later, purulent matter escaped from the wound, the convalescence was otherwise satisfactory and uneventful

I wish to thank Dr Livingston for his co-operation in the management of this case

Herbert F Blackliff, M B, F R F P S,
Honorary Assistant Surgeon North Lonsdale
Hospital, Barrow in Furness.

Reviews

RADIOLOGY OF THE CHEST

IN *The Chest*[1] the latest addition to the *Annals of Roentgenology*, Dr L. R. SANTE has produced an interesting, instructive, and comprehensive yet compact volume, containing information of the utmost value to the physician who needs in the course of his work a knowledge of the interpretation of chest films. The work is well arranged, being divided into three parts. The first deals with the methods used in making x-ray examinations of the chest, the anatomy and physiology of the chest from a radiologist's point of view, and the principles which lie behind the correct interpretation of the findings. In this part the section on the mechanics of respiration is noteworthy for its simplicity. The second part deals with the radiological evidences of disease, and the third with the various diseases of the respiratory organs, their radiological characteristics and differential diagnosis. The text is illustrated by nearly 400 excellent radiograms and by many line drawings, which clearly show the author's meaning. The clinical material in the third part is particularly good, each description having the clarity and conciseness of a thumbnail sketch. The special radiological study of the heart is excluded from this volume. Special interest attaches to the section on the pneumonias, for the radiological examination of patients suffering from pneumonia is not regularly practised in this country, though the author has undoubtedly made out a clear case for its value. He has made the study of radiology in these diseases peculiarly his own, and in consequence much of the information he gives is new. His views on pulmonary syphilis will not meet with general acceptance, for he holds that the lungs are relatively, if not entirely, immune to syphilis. He states that he has not observed an authentic case or met with any proved cases recorded in the literature. Of outstanding interest is his section on pneumonoconiosis, a disease of very great industrial importance. Radiological examination of the lungs affords the only way by which the full extent of the disease can be determined, and this method of examination is more reliable than any other in detecting progress or regression of the condition. The differential diagnosis of pneumonoconiosis is particularly well described and illustrated. Most of the other pulmonary disorders the author deals with clearly and concisely, but he appears to make no reference either to hydatid or to dermoid cysts, both of which should surely find a place in such a volume. By a curious convention practically all the radiograms and diagrams are so arranged that the heart is seen on the right side of the chest, and the lateral views—for example, in Figs. 199 and 200—give an image which is the reverse of that normally seen; points which should be borne in mind by those who are not thoroughly familiar with the interpretation of radiograms. The work may be regarded as an important contribution to the literature both of radiology and of diseases of the respiratory system, and Dr. Sante is to be congratulated on producing a volume which embodies so much personal observation and contains such sound views. His work deserves a place in every medical library, but its price is 20 dollars.

DE ABREU's book on radiological studies of the lungs and mediastinum[2] is a volume of original views, the result of the author's researches in an important branch of radiology. It is divided into four sections, each representing an address given by him during the last few years. In the first section the author details the methods by which he is able to calculate the relative volume of healthy and diseased lung, a point which he claims to be of importance in assessing the prognosis. These methods are applied in the second section to a study of the discrete forms of pulmonary tuberculosis. The third and fourth describe in great technical detail the "radiogeometry" of the mediastinum with special reference to the heart and great vessels of the chest. The author contends that there is a normal measurement for the different vascular shadows, and that it is possible to determine comparatively early arterial disease by careful study of their widths and densities. When the technical difficulties in obtaining a standard radiogram of the chest are considered the question arises whether this degree of precision is feasible, on the other hand, such precise methods have often led to the discovery of important facts. The volume is illustrated by many excellent radiograms and clear line drawings, it is well printed and has a good bibliography. Its interest lies in the originality of its views and in the meticulous care with which the author has studied his subject.

CLINICAL ASPECTS OF THE BACTERIOPHAGE

HOWEVER well supported by evidence, a case that is overstated meets with a somewhat prejudiced reception from those who might otherwise be favourably inclined. Broadly speaking, the phenomenon of the bacteriophage is open to two interpretations: either the bacteriophage is a living infra-microscopic parasite of bacteria, or it is a non-living agent with properties approaching those of enzymes.

D'HERELLE, as is well known, is convinced of the correctness of the former hypothesis, and in a small volume entitled *The Bacteriophage and its Clinical Applications* he has resumed the arguments in favour of this concept. It must be admitted that there is a great deal to be said for his point of view. Life, as he points out, is characterized by certain features: ability to multiply, to adapt to altered environment, and to assimilate without loss of identity; and since the bacteriophage can be shown to possess these characters he argues that it must be living. No doubt it is very galling to d'Herelle, who holds this view so strongly, to find that all are not prepared to accept his interpretation of the phenomenon, but he would do well to remember that his opponents are neither fools nor knaves, and certainly nothing would be lost by treating other people's views with a little more consideration. The chapter on bacterial mutation, in which the author sketches the part played by the bacteriophage in this direction, is interesting and worthy of careful consideration. The views expressed on recovery from and immunity to infectious disease are original and therefore stimulating, though many bacteriologists will disagree profoundly with them. Here, too, overstatements and rash generalizations are to be found which can only detract from the arguments put forward. It is foolish to say that bacteriologists, rather than study the natural disease, persist in inoculating laboratory animals with viruses to which they are "completely resistant" and then observing the result! And to state that in all epidemic bacterial diseases the natural disease is contagious and the experimental disease is not, is simply to ignore facts.

D'Herelle has little use for the orthodox views on immunity. To his way of thinking the bacteriophage is the important factor governing recovery from an infection, though he does allow that the dissolution of the bacteria by the phage liberates antigen the absorption of which gives rise to immunity. Presumably the phenomenon of inflammation is merely a trick played by nature to deceive the unwary student of disease. The chapter on the use of the bacteriophage is of considerable interest, and it must be admitted that the results obtained in the treatment of dysentery and cholera are quite striking. In other diseases such as colitis, sprue, infantile diarrhœa, and coryza the evidence is much less convincing, and the author frankly admits that typhoid fever does not respond to bacteriophage therapy. We cannot help recalling that equally glowing accounts have been given of the therapeutic use of bacterial filtrates, no doubt Bedika would place much of the success obtained with the bacteriophage to the credit of antivirus. However, those who wish to acquaint themselves with d'Herelle's work will find this book of service. It is clearly written and presents a point of view which is refreshingly unorthodox.

DESCRIPTIVE ANATOMY

It would be of interest to enumerate all the textbooks of systematic human anatomy that have been written for the benefit of medical students, and to determine why it is that some achieve a world-wide popularity while others retire into obscurity almost as soon as they are published Probably fashion and tradition have their say in the matter to a considerable degree We have our Quain, Cunningham, and Gray in this country, and it is nice to see foreign textbooks in use by our students, except those which depend for their distinction upon the excellence of their illustrations This is a point deserving of attention The fourth volume of Professor Julius Tandler's Textbook of Systematic Anatomy,[1] which deals with the nervous system, sense organs, and endocrine glands, is remarkable for its sumptuous illustrations, a large proportion of which are reproduced in several colours It is obvious that no effort has been spared to illustrate this textbook in the finest and most attractive style, and the author is to be congratulated on having at his disposal such a superb artist as Hajek

An anatomical textbook of this kind advertises itself by the quality of its illustrations But unhappily this does not seem to be sufficiently realized in England either by authors or publishers, for it would be possible to name at least half a dozen anatomical textbooks which have recently appeared in this country in which the excellence of the text has been more than counterbalanced by the poverty of the illustrations If this is not quickly realized, then translations of the richly illustrated Continental textbooks will be serious competitors with our own publications Certainly this is quite likely to be the case if Tandler's book is translated into English We should be sorry if it were to turn out so, for we do not think the text of this book reaches the high level of our own classics This is not to say that the text is not perfectly adequate for the needs of the average medical student, for the description is detailed and clear Especially noteworthy is the section entitled "Die nervosen Leitungssysteme," in which a connected account is given of the various conduction paths which subserve the functional activities of the nervous system But we miss the "refinements" which might make the book less of a catalogue of data to which little perspective is given In other words, the descriptive part is of the orthodox, cut-and-dried anatomy Debatable points are set down as established facts, and practically no references to literature are given Little time and attention is paid to important variations of normal structure and arrangement which have a very direct application to clinical problems It is for such points as these that the student is most likely to turn to his textbook of anatomy when he reaches the stage of clinical study But these criticisms are not inconsistent with our opinion that this volume of Tandler's *Anatomy* is a very fine production, and that it ranks with those classics of descriptive anatomy which should form an essential part of the library of every medical student and practitioner

MEDICAL TREATMENT IN GENERAL PRACTICE

Compared with the time set apart for the teaching of diagnosis that devoted to inculcating the principles and details of treatment is in most medical schools regrettably small With the object of redressing the balance Professor Harry Beckman has produced a portly volume with the title *Treatment in General Practice*.[2] In it each of the chief diseases of man, exclusive of those that by prescriptive right belong to the legitimate specialties, has had its own peculiar therapy described, as that therapy has been evolved out of the experience of physicians all over the world In every section authorities are quoted freely, and when opposing views are held each side is given sufficient of an innings to make its main contention clear The author looks upon himself as an editor, summing up the main points in a judicial manner and indicating clearly where the claims made by particular workers in any given field have failed when submitted to the test by other observers This method is highly successful, as not only does it offer guidance, but it stimulates thought where a bare recital of formulæ or nursing details merely stifles initiative

Dr Beckman has supported his text with an excellent bibliography In those diseases such as arterio sclerosis and the chronic forms of nephritis, in which the treatment is almost purely that of symptoms, he does not hesitate to point out that the better course is to secure as far as possible the comfort of the patient rather than to make his life a burden by insisting on measures which are irksome and of very doubtful practical value The general plan of the book follows the lines of the ordinary textbooks, in that diseases are classified according to the systems affected —nervous, circulatory, and so on There are also chapters on acute poisoning, burns, and the treatment of certain obstetrical conditions The final chapter embraces a miscellany, such as the treatment of sea-sickness and delirium tremens, methods of sterilizing the skin, and the technique for the administration of glucose No mention is made anywhere of the treatment of the definitely surgical conditions such as appendicitis For this reason a more accurate title would have been "Medical Treatment in General Practice" One or two rather blatant misprints have escaped the eye of the proof-reader, but otherwise the book, both in style and in get-up, deserves nothing but praise, and Dr Beckman has refrained from employing those transatlantic forms of expression which so often jar upon the island-born reader, if they do not completely mystify him

THE CASE FOR CREMATION

In a small book entitled *Cremation*[3] Miss Florence Fidler recalls the primitive methods of surrendering the dead to earth, air, and fire, she asserts that Christianity did not definitely quarrel with the idea of incinerating the dead until the notion of a material resurrection became a dogma, when cremation gradually ceased to be practised in Europe In 1873 Sir Henry Thompson studied the question in Italy, and, realizing the value of cremation as a sanitary reform, urged its immediate adoption in this country Opposition was strong at first, but his vigorous campaign resulted in the formation of a society of sixteen members, including Millais, Tennel, and Trollope, and this body was the nucleus of the Cremation Society An acre of freehold ground, acquired near Woking in 1878, was devoted to public cremation only after the propaganda work of some enthusiasts had extorted a legal judgement in their favour Express parliamentary sanction was obtained in 1902 Miss Fidler surveys the rapid subsequent growth of cremation, especially since the end of the war, noting the peculiar conditions that have affected its history in Germany and France She then gives a succinct account of the process by which the body is reduced to a fine dust, and indicates the various destinies that await the ashes, whether scattered in the garden of rest, inurned in a columbarium, or carried away to distant chosen places

Some attention is naturally devoted to the stock argument that cremation may hinder the detection of crime This objection is adequately dealt with, and others are carefully considered in a separate chapter The author finds that cremation is of moderate cost to the individual, and may even be a source of financial relief to the community In discussing the ethics of the subject she points out that the early advocacy of cremation coincided with the exposition of Darwinism, and of a science that seemed in complete conflict with religion Although the crudity of that time, there still remains the psychological paradox by which a genuine reverence can commit the dead body to the slow process of disintegration, ignoring the considerations that the rights of the dead include safety from violation and from the disturbance that finally overtakes most cemeteries Fire is described as no more "pagan" than earthly burial, merely cleansing and accelerating the processes of nature

NOTES ON BOOKS

We have received the second edition of *Psychopathology: Its Development and its Place in Medicine* by Dr BERNARD HART. In the present edition no material alteration has been made in the body of the book but a new chapter on the conception of dissociation has been added which serves to amplify the writer's position with regard to the respective contributions to psychopathology of Janet and of Freud. We reviewed the first edition of this book at some length (May 7th 1927, p. 839) and the present issue does not therefore require extended comment. It is satisfactory to know that a new edition has been called for, as the monograph is one with which every serious student of psychopathology should make himself acquainted.

There are cynics who doubt whether the newly qualified practitioner of to-day is given to reading the books on conduct in practice which from time to time are written for his moral guidance. It should be otherwise with *General Practice*[1] the latest production of the pen of that genial cynic Dr. ERNEST WARD. Notwithstanding his statement that his book is not intended for those of mature experience there is much in it that should enlighten and entertain the older practitioner no less than the younger. Dr. Ward describes with a pretty wit and many anecdotes how he has met or circumvented difficulties incidental to general practice. If he hazards an opinion on correct conduct he enforces it with a story. He thinks marriage an advantage to doctors and then proceeds to emphasize the necessity for a good wife by describing the varying fortunes of doctors who chose (or were chosen by) tea shop girls and café manageresses. He believes that general practitioners should undertake only minor operations and illustrates the degeneration which often overtakes the practitioner-surgeon with the tragedy of an operator who expected to find an ovarian cyst, became flustered at the appearance merely of ascitic fluid, suggested the existence of a new growth and, finally removed for microscopical examination—a ring-like segment of a very fat pelvic colon! As an incentive to reputable practice Dr. Ward offers a classification of undesirable types into the collector-practitioner who in visiting a house discovers that little James is looking rather pale or that Mary is stooping as if her back was not quite straight, the brigand who treats many grateful patients for nothing in the hope of discovering a well-to-do victim to fleece and the stunt practitioner who administers prolonged and expensive courses of polyglandular therapy to all and sundry. Dr. Ward cheerfully admits that at one time or other he has made most of the mistakes which a medical man may make. He has found that consultants are often opinionated and conceited because they are conventionally speaking *ex cathedra* and do not usually hear of their mistakes. At the same time he impresses on his readers that with few exceptions colleagues are to be considered just as honourable and wise as ourselves and to be treated exactly as we should like them to treat us. Whether there are doctors young or old who require the advice that it looks bad or at least unbusinesslike, to enter a bedroom with a cigarette in the mouth we do not know but we hope they are at least a negligible minority.

The third quarterly instalment of the *Guy's Hospital Reports*[2] opens with an important paper by Dr. L. J. WITTS, who by collecting and critically analysing fifty cases of simple achlorhydric anaemia, establishes the existence of this form of anaemia in a way which the previously recorded cases had not effected. It is common especially in middle-aged women and the achlorhydria, which may be hereditary or acquired precedes the chlorotic microcytic, and secondary anaemia and persists after the anaemia is cured. The proper treatment is by transfusion or iron in twice the maximum pharmacopoeial dose and must be continuous to prevent relapse. The administration of liver preparations and hydrochloric acid has no effect on the anaemia. Great interest attaches to its relation to Addison's anaemia. It is probable that they both depend on achlorhydria which in males more commonly induces a megalocytic anaemia and in females a microcytic anaemia. In both forms the bone-marrow is hyperplastic with in one predominance of megaloblasts in the other of normoblasts. Glossitis and splenomegaly occur in both subacute combined degeneration usually associated with Addisonian anaemia, may also occur in simple achlorhydric anaemia. Dr. H. G. CLOSE contributes a very interesting article on the hospital incidence of certain diseases showing by comparison of the two five-year periods 1910-14 and 1921-25 inclusive those diseases which have become more frequent less frequent and have remained stationary. Lobar pneumonia rheumatic fever chorea and therapeutic anthrax have like typhoid fever and chilblains generally recognized become less common while tuberculous adhesions anaemia Hodgkin's disease and talipes dorsalis have not shown any change. Dr. V. F. HURST and Mr. J. GARMER JONES describe megalo-ureter due to achalasia of the ureterovesical sphincter and Mr. Ralph THOMPSON reports the cases of vesical calculi during the period 1910-29 inclusive. Dr. J. T. IRVING writes on the permeability of the renal cell to glucose and Mr. CLIBBORD in his report of the maternity department considers the low incidence of eclampsia to be in part at least due to a fortunate local rarity. Cases of duodenal retroperitoneal hernia are reported by Dr. VENABLES and by Mr. P. TURNER and Mr. SCHOLEFIELD. Mr. BROMLEY reports cases of obstruction of the small intestine due to foreign bodies such as gall-stones, to inflammation in or around the intestinal wall, and to new growths.

The first number of the *Collected Publications from the Robert Dawson Evans Memorial for Clinical Research and Preventative Medicine*[10] (Boston Mass.) is devoted to endocrine studies reprinted from *Endocrinology* and is dedicated to the living memory of Maria Antoinette Evans the Founder. The work began in 1912 and during these seventeen years between four and five thousand persons have been investigated clinically and by laboratory methods. The first paper, describing a general method for the differential diagnosis of abnormal endocrine function is by Dr. A. W. ROWE and contains an analysis of a thousand cases thus investigated subsequent examination of more than two thousand cases confirmed the conclusions in this paper which was published in 1922. The last paper also on the differential diagnosis of endocrine disorders, and published in August 1929 is by Dr. ROWE. The other seven papers are contributed by Dr. ROWE in collaboration with Dr. C. H. LAWRENCE, and deal with disorders of the pituitary thyroid, gonads and adrenals with pluriglandular disease, and five hundred cases simulating endocrine disorders. The collection is a monument of laborious investigation, and is strikingly illustrated.

A booklet entitled *The Problems of Rinderpest in India*,[11] by the late director of the Imperial Institute of Veterinary Research Mukteswar, India describes what is the most formidable cattle scourge in India and discusses the methods of control of the disease. The disease is essentially one of cattle and the author describes how the virus has been attenuated by passage through goats, and how this attenuated virus may be used for the vaccination and protection of cattle.

PREPARATIONS AND APPLIANCES

A RECTAL SUPPORT FOR ANAL PROLAPSE.

DR. E. J. LLOYD (Bangor) writes: In the course of more than fifty years as a general practitioner I have had several cases of prolapsus ani especially in old people where an operation would not be advisable. I could never obtain a satisfactory support in these cases, so I had to devise one myself.

First I found I must have a well-made padded leather belt buckling in front. This was supplied by Messrs. Ellis Son and Paramore, Sheffield, and the appliance was completed as follows on my instructions. A thick rubber piece is folded on itself in the middle part but leaves a loop at the top and one at the bottom. This rubber piece is about 8 or 9 inches long and about 3 inches wide. One end of the belt is passed through the upper loop and on to the middle of the belt. The under strap is made of a round rubber piece with leather bands attached to each end; there are holes in it for fastening it to studs one on each side of the front of the belt. The under strap is passed through the lower loop of the rubber central piece as far as its middle. A rubber plug is unnecessary and uncomfortable to wear.

After every act of defaecation the prolapsed portion of the rectum must be carefully returned by pressure upwards with the fingers of the right hand. It is then bathed with a pad of cotton wool dipped in a weak solution of an antiseptic such as liquor carbonis detergens (no. lysol) and subsequently dried with a piece of cotton wool. It is advisable to place a piece of cotton wool of about 4 by 3 inches to cover the anus and to bring the rubber piece over the wool. The rubber piece should be washed frequently.

ABORTION AS A CAUSE OF MATERNAL MORTALITY

REPORT OF THE HEALTH SECTION OF THE LEAGUE OF NATIONS

THE interim report of the Ministry of Health's departmental committee on maternal mortality and morbidity[1] treated of abortion only briefly, in the monthly epidemiological report of the Health Section of the League of Nations for July[2] the question has received considerable attention, and a striking analysis of the available statistics is included. The significance of abortion as a cause of maternal deaths has only gradually been appreciated, as a reference to the international list of causes of death shows. Thus, in 1920 abortion was included under the general heading of "The puerperal state," and under the subheading "Accidents of pregnancy," but in 1929 it is given much more prominence, and classified as "abortion with septic conditions" and "abortion without mention of septic conditions, but including haemorrhage." The change represents not only an alteration in medical opinion but the appreciation of an important social factor, introduced by the increase in the number of abortions. Indeed, the report states categorically that the maternal death rate is more affected by abortion than by delivery at term.

Prevalence of Abortion

The legalization of abortion in Soviet Russia has already brought some interesting points to light, and will provide an opportunity for a thorough investigation of the problem as the public mind becomes more accustomed to the experiment. In the report of the Aberdeen Commission for the past ten years, the death rate among unmarried mothers was recorded as being almost double that of married mothers, while the puerperal death rate among them was three times that among married women. It is true that many unmarried mothers experience their confinements under less favourable conditions than the average married woman, and consequently stand a greater chance of developing puerperal infection, but it is also usually accepted that abortion, which is one of the primary causes of maternal mortality, is more frequent among unmarried women. In Russia the statistics for 1925 and 1926 show that the number of abortions, and hence the number of deaths, was higher among women whose marriage had not been registered, they also indicate that abortion is more frequent at the second pregnancy than the first. In countries other than Russia, of course, the difficulties of obtaining reliable statistics are insuperable.

Two factors enter into a study of abortion—the real or probable number of abortions in a country, and the proportion which lead to disease or death—and in neither case is it possible to make an accurate estimate. In Germany, according to certain investigators, abortions have risen from 240,000 in 1911 to more than a million in 1927, taken in conjunction with the birth rate these figures work out at 1 abortion to 8 confinements in 1911 and nearly 1 abortion to every confinement in 1927. But it is improbable that these estimates do more than guess at the truth, as the conflicting opinions of different authorities show; Walthard, in 1929, estimated the number of women who succumb to the operation at 15,000, while in 1926 Lippmann calculated this number at 35,000. The difference in economic conditions between the two years in question may have a bearing.

A certain amount of information can be gleaned from hospital records, and Professor Whitehouse has analysed the figures for abortions among 1,000 parturient women at the Birmingham General Hospital from 1924 to 1928, 3,228 children were born, and abortion occurred in 597 cases. In a similar inquiry made between the years 1911 and 1913 the proportion of women who had at least one abortion was 35·3 per cent. An estimate made by Professor Grzywo-Dabrowski at Warsaw is quoted which puts the rate at 1 abortion to 4·15 confinements, but these figures only relate to serious cases treated in hospital, and consequently merely give some indication of the morbidity due to abortion.

According to a report submitted to the National Association for the Prevention of Infant Mortality in 1929 by Dame Louise McIlroy, abortion since the late war is more frequent among married than unmarried women, unemployment and economic difficulties are mentioned as the chief causes of this transposition, and the opinion of Professor McIlroy is borne out by the experience of three observers in America, who found that among 672 deaths due to abortion 610 occurred among married, and only 60 among unmarried women.

Abortion in U S S R

Some of the most interesting figures quoted relate to Russia, where 80 to 85 per cent. of abortions are believed to be registered owing to its legalization. Here the average in the towns is said to be 25 abortions to 100 confinements, and higher in the large cities, reaching 70 per 100 confinements in Moscow. The proportion of abortions is said to be from 8 to 10 times greater in large cities than in country districts and small towns—possibly, suggests the report, owing to the fact that prejudice dies hard in rural districts, and hence secret abortion is more common and registration is less complete. Legal abortions are carried out in the hospitals, generally during the second month of pregnancy, while secret abortion is frequently practised at a late stage of pregnancy, adding considerably to the maternal danger. This may be compared with the state of affairs in Germany, where Lippmann estimates that some 35,000 women die yearly from complications of abortion, unhygienic conditions and the late stage of pregnancy at which secret abortion is carried out accounts for the high mortality rate.

Further Russian statistics show that abortion is most frequent between the ages of 20 and 39. A series of statistics of the age groups in cases of puerperal fever following abortion obtained in Prussia show that the greatest number of abortions occur between the ages of 30 and 40—that is to say, among women who have probably previously borne children. Another point emerging from Russian experience is that the number of abortions does not necessarily increase as a result of legalization, while the decline in secret abortions during the last few years and the performance of the operations in hospital have been accompanied by a corresponding decrease in maternal mortality. The death rate for legal abortions performed in hospital is very low, and in Moscow during 1926 artificial abortion was practised on 29,306 women without a single death, while among women admitted to hospital following secret abortion the death rate reached 1·2 per cent. Whatever arguments may be urged on moral or other grounds against the legalization of abortion in U S S R it appears to have been effective in preventing the shocking waste of maternal life. Whether in the long run the waste of infant life will more than counterbalance this gain remains to be seen.

Analysis of Abortion Statistics

Roesle is quoted as urging the compulsory notification of abortion in every country, but, as the authors of the report point out, it will never be possible to induce people to notify an operation which is punishable by law. Members of the medical profession are not prepared to register a fact which may be injurious to their patients, regarding it as a breach of professional confidence. Holmes, Mussey, and Adair, who analysed statistics of accidents of pregnancy occurring before the seventh month in the United States of America, found that among 672 registered abortions 189 were classified as spontaneous, 69 as therapeutic, 328 as induced, and in 89 the cause was not specified. Experience has shown that in the large towns many cases of abortion are induced, but are classified as therapeutic so

[1] *British Medical Journal*, August 9th, p. 223.
[2] Monthly Epidemiological Report of the Health Section of the Secretariat. Ninth Year, No. 7. Geneva, July 15th, 1930. 1s. 6d.

as to avoid the attention of the judicial authorities, abortion therefore probably plays a large part in the maternal mortality of the United States and if the unregistered were added to the registered cases the number of deaths would be at least equal to those caused by accidents of pregnancy and labour The same observers found that deaths due to abortion were less common in the series among white women than among negresses probably owing to the difference in economic conditions between the two races They estimate that puerperal sepsis is responsible for death in 90 per cent of deaths following induced abortions and in 60 per cent of so-called spontaneous abortions Swiss statistics show that during the last thirty years maternal mortality following puerperal fever has been reduced by half but that deaths due to abortion remain at a high level and exceed 20 per 1,000

Causes of Increased Abortion Rate

Mme Lebedeva, head of the Maternal and Infant Welfare Section at the Soviet Commissariat of Public Health considers one of the causes of the increase in abortion to be the enormous increase of women workers which has occurred in every country the housing shortage and the decline in economic prosperity have played a part and the decrease in infant mortality which has been considerable in most countries during the last twenty years, has doubtless thrown an additional burden on the poorer class of parent which has made the avoidance of further responsibility seem all the more urgent

THE INTERNATIONAL SILICOSIS CONFERENCE AT JOHANNESBURG

[From our Pretoria Correspondent]

The conference on silicosis convened by the International Labour Office of Geneva was held in Johannesburg at the offices of the Transvaal Chamber of Mines during the fortnight August 13th to 27th At the opening meeting the chair was taken by Mr J J Phelan, chief of the diplomatic division who explained that the International Labour Office was the executive secretariat of the International Labour Organization, a society comprising fifty six States which had entered into a contract that they would collaborate in improving the conditions of labour In the constitution of the organization industrial disease was specifically referred to, and one of the sections of the Labour Office was devoted to the study of this subject Owing to the distance of South Africa from Geneva a conference though approved by the International Labour Office, would probably never have been held but for the generosity of the Transvaal Chamber of Mines

All the Governments whose minds have been exercised by the incidence of silicosis were represented at the conference Australia by three members Canada by one Germany by two, Great Britain by four, Italy by one the Netherlands by one, the Union of South Africa by ten, and the United States by two members The International Labour Office was represented by three members of the diplomatic division, and by two members of the Industrial Health Service, including Dr L Carozzi the technical adviser At the first business session Dr L G Irvine, chairman of the Miners Phthisis Medical Bureau, Johannesburg, was elected chairman of the conference Sir Spencer Lister, director of the South African Institute for Medical Research, and Dr A L Russell of the United States Public Health Service, were elected vice-chairmen In accordance with the usual Geneva procedure a resolutions committee and "reporters" on the three sections into which the subject was divided were also elected Their reports, after amendment by the full conference, will eventually be published in a volume, which will include the various papers submitted beforehand and an account of the proceedings

Preventive Measures

The reporters elected for this part of the discussion were Professor Lorigo, chief medical inspector of factories Italy, Dr Badham, medical officer of industrial hygiene of the New South Wales Department of Public Health and Mr Roberts technical adviser to the Transvaal Chamber of Mines All the papers submitted under this and other sections which had been printed in General and previously circulated were not read at the meetings but their substance was discussed on broad lines, members freely expressing the results of their own experience

The discussion indicated that silicosis becomes noticeable after widely differing periods of exposure, it is contracted through inhaling for a sufficiently long period dust containing percentages of silica as low as or even lower than 30, the greatest amount of harm is done by the smallest particles those less than about 3 microns in size Some evidence was adduced in favour of the value of other particles, such as coal or shale dust, inhaled simultaneously with silica dust but experience, particularly in Germany, was definitely against the prophylactic value of alternate employment in silica and coal mines The alleged immunity from silicosis in some districts where quartz in company with non siliceous rock was being mined was unfounded the incidence of silicosis had been obscured by the migratory nature of the population and by the inadequacy of medical examination where not required by laws relating to compensation It was generally agreed that the power of resistance of the individual was an important feature Evidence was also forthcoming that alternative employment and periods free from exposure to silica dust delayed the formation of silicosis some members, however, maintained that it was only the total periods of exposure which mattered, whether such periods had been continuous or not It was strongly urged that for the critical and scientific study of dust particles a standard method of assessing the dust content of air, both by counting and gravimetrically, was required Only if assessed by such standard means would the findings be available for international comparison The conference recommended that as soon as such standard methods had been perfected a complete survey of the dust concentration in dusty industries throughout the world should be made

For the prevention of dust in the Witwatersrand Mines greatest reliance has always been placed on the use of water Water is sprayed into the air all surfaces of the rock where work is being done are kept wet with the object of securing a fly paper effect in retaining dust which might settle on them, water is applied to the point of percussion—for example by means of an axial water feed in drills Only the third of these methods was considered to be of any real value in the prevention of silicosis The very small particles of silica which are responsible for silicosis are not likely to settle on roofs and walls and like micro-organisms of the same size will not be caught by a spray Unnecessary humidifying of the air is to be avoided particularly in the deep mines, where it interferes greatly with the cooling mechanism of the body by preventing evaporation of sweat, a humid atmosphere and the presence of droplets have been shown experimentally to increase the risk of various infections considerably

Other methods of dust prevention investigated were the application of exhaust draughts at or near the point of origin of the dust, dust traps, masks, and ventilation Some years ago experiments were conducted on the Witwatersrand to maintain the surface of underground walls and roofs in a condition to cause dust particles to adhere to them They were sprayed with solutions containing molasses calcium chloride and other hygroscopic substances but in the humid atmospheres produced underground these substances were found to absorb moisture so readily that they soon trickled down into the gutters

Medical Aspects of Silicosis

The reporters in charge of this portion of the discussion were Dr L V Gardner of the Trudeau Sanatorium Dr A J Orenstein the superintendent of

sanitation of the Rand Mines, Ltd , Dr E L Middleton, medical inspector of factories, Great Britain, and Dr W Steuart, radiologist to the Miners' Phthisis Bureau, Johannesburg

Silicosis was defined as a pathological condition of the lungs due to inhalation of silicon dioxide, which could also be produced experimentally in animals To produce the condition the silica particles must reach the lungs in sufficient amount, over a sufficiently long period of time, they must be less than 10 microns in size, and must be chemically uncombined The minimum time and concentration have not yet been determined they appear to be to some extent reciprocally variable Experimental evidence indicates that the solubility of silica in the tissues is the essential factor in the causation of silicosis The progress of the silicotic condition is unfavourably influenced by infection of the lung with pathogenic organisms, tuberculous infection being especially bad Other dusts, harmless in themselves, are capable of producing serious pneumonoconiosis in a lung in which the silicotic process has been established Opinion varied as to whether intermittency of employment retarded the onset of silicosis The local evidence regarding native labourers, who work for periods of about nine months at a time separated by varying periods at their kraals, tends to indicate that intermittent employment is less harmful than continuous employment of the same total length

Pathologically five stages of the disease are recognized First, there is a fine bronchiolitis characterized by an accumulation of dust-filled phagocytes in the terminal bronchioles, then an accumulation of dust containing phagocytes about and in the intra-pulmonary lymphoid tissue and then transportation through the lymphatics into the tracheo-bronchial lymph nodes It is not until the next stage is reached that the condition constitutes silicosis in the legal sense Thus stage is characterized by the gradual development of fibrous tissue within the mass of phagocytes and the formation of a characteristic nodule in these foci Finally, the hyaline nodules increase in size by extension at their periphery, coalescence of adjacent nodules takes place and brings about involvement of extensive areas of the lung

Clinically three stages can readily be recognized In the first stage respiratory symptoms may be slight or absent, working capacity may be slightly impaired, there is a departure from normal of physical signs, and the radiogram shows dense linear and nodular shadows In the second stage all the physical signs are increased, the nodular shadows are increased in number and size, and there is some degree of definite impairment of physical capacity In the third stage all signs and symptoms are greatly exaggerated, and there is total loss of working capacity Pulmonary tuberculosis may be present in any of the stages, altering the symptoms, physical signs, and the degree of incapacity The reporters recommended the establishment of an international classification of silicosis an internationally comparable radiographic technique and terminology, and the institution of further studies in the correlation of radiographic appearances and morbid anatomy of silicosis and silicosis complicated with tuberculosis

Diagnosis Compensation and After-care

The reporters for this section were Dr G Cunningham, director of the Division of Industrial Hygiene of the Colman Health Department Professor A J Hall of Sheffield University (Chairman of the Medical Research Council Committee to investigate pulmonary diseases from silica and other dusts) and Professor Koelsch, State medical officer Munich Germany

It was considered that silicosis whether complicated or not involve constituted an occupational disease reduction of working capacity In a medical examination to ensure a certain standard of physique should be generally adopted in industries in which the risk of exposure to silica dust is great Periodic examination of such workers is also essential Whether it is in the worker's interest to leave the industry in the early stage of the disease was not clearly established South African experience suggests that downward progress is not generally arrested on leaving the industry It is probable that reduced economic conditions of life consequent upon leaving a highly paid industry and the associated mental worries are largely responsible for this On the other hand, continuation in underground employment appears definitely to aggravate the progress of the disease except in certain selected mining occupations

The conference recommended that in assessing the amount of disability account should be taken of the clinical and functional condition as a whole The determination of disability should be entrusted to an independent medical expert, or body of experts, possessed of the requisite clinical and technical knowledge and provided with suitable apparatus It was suggested that removal from all industrial occupations involving exposure to noxious dust should be enforced in all cases of open tuberculosis Where legislation provides for the compulsory removal from occupations involving exposure to silica dust of workers affected by silicosis, it was suggested that such compulsory removal should not necessarily be applied to workers who have been in the same industry for a period of not less than fifteen years and have reached the age of 45 years

Regarding after-care, the conference recommended that sanatorium treatment should be provided for suitable cases Rehabilitation schemes, such as farm settlements, have in most cases proved unsuccessful in the past Further investigation into this problem was strongly urged

ROYAL MEDICAL BENEVOLENT FUND

AT a recent meeting of the committee thirty six grants were made, amounting to £655 10s 6d The following are particulars of a few cases helped

M B B Ch aged 36, married with three children aged 5, 3, and 1 A medical man writing in support of the case says The applicant is a general practitioner in this town who put up his plate some twelve or eighteen months ago and who unfortunately two months ago developed rheumatic fever He is now in hospital He is a married man with three children He has no reserves and is therefore falling into debt having his wife and family to maintain and to pay a locum tenent at the same time Voted £20 and further help is being sought from another charity Case will be reconsidered in three months time

Daughter, aged 46 of M B B S Father died at the age of 80 this year A medical man, writing in support of the case says I was intimately associated with her late father one of Nature's gentlemen who worked hard in a poor-class practice for over fifty years often—too often, alas!—without any remuneration whatsoever For about four or five years before his death he was an invalid and for over a year was bed ridden During all this time he was nursed by the applicant, whose devotion to him was exemplary Voted £20 It is hoped that the applicant will soon be able to find employment for which she is trained

Daughter aged 65, of M D At the death of her father in 1894 the applicant was left quite unprovided for and untrained in any way to earn her own living consequently she had to go out into the world to do what she could She became a housekeeper at a girls school Present income £52 a year Voted £26

Widow aged 62 of M R C S, I R C P The husband was in receipt of an annuity from this Fund as he had broken down in health, he also had a pension of £51 a year On his death in 1930 both the annuity and pension ceased The widow's sole support is her daughter, who is earning 52s a week Voted £26 help will be sought from other charities

Widow, aged 70 of M B Since the death of her husband in 1897 the applicant has worked as a nurse companion A medical man writing in support of the case, says She worked for nearly thirty years as a nurse-companion and now lives with two sisters daughters of a medical man also in very reduced circumstances They club together and just rub along somehow The applicant is getting on in life and is not fit to do much now except look after herself I resent income £55 Voted £26

Subscriptions and donations are very urgently needed in order that the activities of the Fund may be continued and applicants given the help they need Cheques should be forwarded to the Honorary Treasurer, Royal Medical Benevolent Fund, 11, Chandos Street, Cavendish Square, W 1

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys The Guild appeals for second hand clothes and household articles The gifts should be sent to the Secretary of the Guild, Tavistock House (North), Tavistock Square, W C 1

SATURDAY OCTOBER 4TH, 1930

NASOPHARYNGEAL INFECTIONS

THE climate of this island during the winter months, coupled with the conditions that prevail in our great industrial cities, is responsible for an enormous amount of respiratory disease and yet we know remarkably little about the causation of these infections. In stating this reference is not being made, of course, to the pneumonias of pneumococcal and streptococcal origin—though in the case of the latter organism it is not clear how far it can act alone in this role—but to that multitude of infections of the respiratory tract which occupy so large a place in our national bill of health and lead to a considerable loss in efficiency and working time. It has become the habit to attribute these infections to the pneumococcus, the streptococcus, the haemophilic bacilli, or to Gram-negative cocci such as *Micrococcus catarrhalis* (*N. catarrhalis*) for the obvious but not very good reason that these bacteria are all that can be found by a microscopic and cultural examination. But at the back of the minds of many has been the thought that these organisms are merely secondary invaders, and that the prime cause for the time eludes us. Direct experiment in this field has been hampered by the lack of a suitable experimental animal. Apart from man the higher apes alone would appear suitable, and their use is limited for obvious reasons. That they are of service, however, has been demonstrated by the recent work of Dochez and his colleagues[1] in the United States by the use of the chimpanzee; these workers have obtained evidence which strongly suggests that the common cold is caused by a filterable virus.

Another mode of approach to this question would be to observe over a considerable time the flora of the respiratory tract of a representative sample of a community, and to compare the findings with the incidence of respiratory diseases, noting correlative fluctuations. Such an experiment has been conducted in Manchester by R. H. Blackburn, R. B. Boston, E. St. G. Gilmore, R. Lovell, S. P. Wilson, and Mrs. M. M. Smith, and their findings are embodied in a report to the Ministry of Health.[2] This investigation extended from July 1925 to September 1927, and during this period the nasopharyngeal flora of one hundred volunteers, drawn from different environmental conditions, was examined at monthly intervals. In addition to this, between November 1925 and August 1926 one hundred volunteers who were examined once only, were drawn each month from a variety of sources. The bacterial species envisaged were the pneumococcus, the influenza bacillus, the haemolytic streptococci, and the Gram-negative diplococci. Briefly stated the results were as follows. Both in the winter and spring of 1925–26 and 1926–27 there was a considerable increase of respiratory disease in Manchester, but whereas in the former period there was little or no influenza, the latter period was marked by an epidemic wave of influenza of moderate severity, which reached a peak in March 1927 and thereafter rapidly declined. During the period of survey the carrier rate of Gram-negative diplococci in the sample community remained at a uniformly high rate, the only finding of interest being the comparative rarity of *Micrococcus catarrhalis*. Although the carrier rate of both the pneumococcus and haemolytic streptococci showed fluctuations, these bore no significant correlation with the incidence of respiratory disease. In the case of the influenza bacillus, however, the findings were more significant. Taken as a group the carrier rate curve of haemophilic bacilli closely followed the curve of incidence and mortality from respiratory disease, but not the curve of influenza mortality, for as has been already mentioned the winter and spring of 1925–26 were marked by an almost complete absence of influenza.

Nevertheless, as the authors of the report point out, the group of haemophilic bacilli would not appear to be a homogeneous one. The only biological character affording a sharp line of demarcation within the group is the ability to form indol, and when the incidence of indol-forming haemophilic bacilli was plotted separately it was found to bear a significant relationship to the incidence of influenza. The carrier rate of these indol-producing strains began to rise some two months before the onset of the influenza epidemic, and then fell away fairly rapidly. It must be admitted that this observation is of considerable interest. Naturally it does not prove that influenza is caused by the indol-producing strains of the influenza bacillus, but it is a valuable piece of circumstantial evidence. It should be remembered also that had Fleming's method of isolating the influenza bacillus been adopted a totally different carrier rate would have been obtained. Fleming[3] has shown that with suitable technique these organisms can be demonstrated in practically every nasopharynx, so that an increased carrier rate in this investigation in reality means an increase in the number of these haemophilic bacilli in the flora of the individual nasopharynx. Whether this would apply also to the indol-producing strains it is impossible to say, but the findings in this report are sufficiently interesting for us to hope that similar investigations with modifications such as the use of Fleming's method of isolating the influenza bacillus will be undertaken. Information of considerable value in forecasting influenza epidemics might be forthcoming.

[2] Blackburn, R. H., Boston, R. B., Gilmore, E. St. G., Lovell, R., Wilson, S. P., and Smith, M. M. R. Reports on Public Health and Medical Subjects, No. 57, 1930. London: H.M. Stationery Office.

ANNUAL REPORT OF THE MINISTRY OF HEALTH

THE annual reports of the Ministry of Health are not, it must be confessed, inspiring documents. The Chief Medical Officer of the Ministry, in his own reports (which are published separately) makes an annual survey of the health of the nation, he describes the scope and achievements of the public health services, discusses the principles and ideals of preventive medicine, and sets out the problems, medical and social, upon whose solution the attainment of these ideals depends. His reports serve both as records of progress and as signposts to the future. Less obviously, yet surely, the statistical analyses issued by the Registrar General—above all, his analyses of occupational mortality, fertility, and infant mortality—indicate the triumphs as well as the tasks of preventive medicine by their quantitative demonstration of the influence of environmental factors on individual and social

[3] Fleming, A., *Brit. J. exp. Path.*, 1929, 10, 226.

health they point plainly to causes of sickness and death which the health services of the nation must ultimately bring under control Set the difficult problem of not overlapping with these documents, the Ministry of Health can do little except record the more important business it has transacted during the year, presenting bald administrative detail in connexion with international health work, general health questions, sanitary administration, inspection and supervision of food, infectious diseases, maternity and child welfare, welfare of the blind, housing of the nation, town planning, local government and local finance, administration of the Poor Law, national health insurance, and many kindred matters, and offering if not a very exciting, at any rate a useful report from which the careful reader may gather some idea of the range of services with which this comparatively young Ministry now has to deal

Under the heading "Inspection and Supervision of Food" the Ministry describes in the report for the period 1929-30[1] the new procedure that has been adopted in connexion with the tuberculin testing of cattle The Tuberculin Committee having issued a report in 1929, in which it stated the conclusion that the modified double intradermal test was simpler to apply and gave better results under ordinary farm conditions than the subcutaneous test, and that the ophthalmic test was unreliable, the Ministry, in January, 1929, informed graded-milk producers that the ophthalmic test was no longer needed, and that the question of requiring the modified double intradermal test to the exclusion of the subcutaneous test would be considered at the end of the year After further consideration it was decided to make the new test compulsory, and at the close of last year licencees were informed that all tuberculin testing of licensed herds must be made by this method During the twelve months under review 133,584 samples were analysed under the Food and Drugs (Adulteration) Act, 1928, and of these 7,260, being 5 4 per cent of the whole, were found to be adulterated or not up to standard In the same period 511 contraventions of the Food Preservatives Regulations were reported, a reduction of 264 on the figures for 1928 A few samples of graded milks, though complying with the conditions of the Milk (Special Designations) Order, 1923 as to bacterial purity, were reported to contain less than 3 per cent of fat, and one analyst has expressed the opinion that fat deficiencies in graded milk occur frequently, and seem to be due to the methods employed in bottling In the section dealing with infectious diseases attention is drawn to the fact that the number of notifications of encephalitis lethargica and the number of deaths from that disease were practically equal, any fatality rate calculated on these figures would, the report states, be "merely artificial, and not representative of the true rate" Although mild small-pox continues to prevail there has been a further decline in the number of cases notified A slight increase is recorded in notifications of diphtheria, and a considerable increase in notifications of scarlet fever and pneumonia, the fatality rates for diphtheria and scarlet fever have, however, remained low, though the decline recorded in previous reports has not been maintained

In connexion with tuberculosis, the announcement is made that Dr Camac Wilkinson's method of administering tuberculin treatment is about to be investigated under the supervision of representatives of the Medical Research Council, the London County Council, and the Ministry itself Attention is again drawn to the fact that in certain areas a large proportion of cases of tuberculosis do not come to the knowledge of medical officers of health until death has taken place, and the Ministry suggests that in such areas the local authority should take every opportunity of reminding medical practitioners of the facilities available under the tuberculosis schemes for the diagnosis of doubtful cases, through consultation with the tuberculosis officer, examination of sputum, *x*-ray examination, and so forth At the venereal diseases treatment centres the outstanding features of the year's work have been the continued increase in the total attendances at out patient clinics, the increase in the number of cases of gonorrhoea, and the decrease in the number of cases of syphilis The figures bear out the view that a larger proportion than formerly of gonorrhoea patients now attend the centres, though the proportion still falls short of the estimated relative incidence of the two diseases

During the year under review 14,600 doctors were engaged in practice under the National Health Insurance Acts, and the number of insured persons entitled to benefit was over fourteen million Medical benefit cost £8,666,000, of which sum medical practitioners received £6,256,000 in respect of their duties in connexion with attending and treating insured persons, the balance covering pharmacists' fees, and the cost of effecting adjustments of the main finances of medical benefit to various special conditions arising under the Acts or in the circumstances of insurance practice It is pleasant to read that with the co-operation of the Insurance Acts Committee of the British Medical Association 113 doctors practising in sparsely populated country districts have received financial help enabling them to attend courses of post graduate study, as compared with the previous year's figure of 89 When the British Post Graduate Hospital and Medical School comes into existence we may hope for a large increase in the number of practitioners, rural and urban, attending "refresher courses"

These miscellaneous facts have been taken almost at random from the report, and serve, not as an epitome of its contents, but merely as a very rough indication of their nature The report covers so great a variety of topics that it is impossible to extract from it an essence for easy administration in a column or two of print It is to be commended, not as embodying material to be studied systematically, but as a work of reference For the latter purpose it is invaluable

PREVENTION AND TREATMENT OF CRIME

Among a number of interesting papers in the current issue of the *Howard Journal* is a thoughtful contribution by Dr R D Gillespie, on the service of psychiatry in the prevention and treatment of crime The psychiatrist, as such, is professionally in a position which requires him to take a strictly objective view of crime and criminals His functions are to study the factors, both those residing in the psychic peculiarities of the delinquent himself, and those conditioned by his environment, which appear to have exerted an influence in the determination of his anti-social behaviour, and also to suggest methods of dealing with the "patient" which may be instrumental in bringing about a "healthy" social reaction Dr Gillespie observes that the psychological contention of crime is that, like mental illness, it is a symptom—a symptom of indi-

vidual maladaptation to the social environment Crime is not as a rule the outcome of mental illness in the ordinary sense, although there is a small percentage which definitely is so but a cognate manifestation of social maladjustment Crime, in many of its instances, and mental disorder, are on this view on a parity for investigations of the life history of criminals and offenders, after the manner in which the mentally sick are investigated, have shown that similar factors are often at work There are, for instance, *the more crude and obvious causes, such as defective home* environment and training and also the more personal and less conscious factors, which involve repression and perversion of instinctive trends Psychiatry has already contributed much to the problem of crime by recognizing that it appears more easily in certain types of individual than in the average person submitted to the same temptations and opportunities Dr Gillespie points out that the recognition of several types of antisocial persons should enable us to forestall the appearance of criminal acts in individual examples of such types A number of delinquents are obviously mental defectives Estimates of the proportion of these vary a good deal, but some of these are distinctly high Thus, of the inmates of reformatories, training schools, workhouses, and penitentiaries in the United States, where fairly complete surveys have been made, 31 per cent , Dr Gillespie states have been found to be mentally defective It is the so-called borderline defective, with sufficient intellect to pass muster on ordinary inspection, but with deficient foresight and emotional control, who is difficult to detect, or, if detected, to handle effectively Here the preventive diagnostic service of clinical psychology has to be reinforced, when practicable, by additional legal protection It too often happens at present that no treatment can be enforced, because the patient is not sufficiently defective to be certifiable, or because there is no available accommodation Then there is another group, proportionately larger in prison populations than that of the intellectually defective, which is also capable of diagnostic prediction They comprise according to some statistics, as many as 45 per cent of the prison population These are the so-called "psychopathic personalities" It is obvious that, apart from the general social conditions which nourish crime, preventive measures are indicated, especially with the psychopathic types and with the mentally defective Early diagnosis before antisocial acts appear is not only desirable but possible Still better is it, as Dr Gillespie suggests, to prevent the creation of psychopathic personalities, for since many of these begin to be created in childhood, it is clear that, so far as psychological measures are concerned, prevention must begin then At the present time it may certainly be said that the facts referred to above are being increasingly appreciated In all directions active measures are being taken to prevent the development of delinquent traits in children, and to treat them along psychological lines when they first make their appearance Thus child guidance clinics, special schools and classes for the backward, voluntary associations which supplement the work of statutory committees, advisory psychiatrists in connexion with the children's and juvenile courts, and the education of teachers in regard to the significance of abnormal traits in their pupils—all such developments and organizations are calculated to do something to diminish the incidence of delinquency in the community In addition to the paper on which we have commented *the Howard Journal* contains a number of other interesting contributions A condensed account of the evidence given before the Select Committee on Capital Punishment, in which the attitude taken by each witness is broadly outlined, will be found very helpful to those who are interested in this important social problem

CALCUTTA SCHOOL OF TROPICAL MEDICINE.

The formal teaching of tropical medicine is so commonly associated with the schools in London, Edinburgh, and Liverpool that it is too often forgotten that the British Empire possesses another active and flourishing school in Calcutta The annual report for 1929[1] shows how extensive and many sided are its interests, both in teaching and in research The school is under the directorship of Lieut.-Colonel Acton, and is organized both as a school of tropical medicine and an institute of hygiene It is now common knowledge that the Government of India has accepted the munificent offer of the Rockefeller Foundation to build and equip an All India Institute of Hygiene in Calcutta, which would carry out teaching work in close co-operation with the School of Tropical Medicine Lieut.-Colonel A D Stewart has been appointed to act as director-designate, and a site is now in the process of being acquired and provisional plans have been made When this institute is ready opportunities for research and instruction in the problems of public health will be available for students and workers in India, with special reference to Indian conditions With the development of public health policy all over India on more concrete and definite lines the need for well-trained workers will become more and more necessary, and it is hoped that the new institute will supply the needs of India in this respect In addition to the teaching at the Tropical School, the work of the Pasteur Institute, and the Carmichael Hospital for Tropical Diseases, there is a special staff working in the Leonard Rogers Laboratories on leprosy, kala azar, hookworm disease, bowel diseases, diabetes, filariasis, and many other subjects of importance to medicine and hygiene in India That the work carried out in Calcutta is active and comprehensive is shown by the fact that over eighty papers were published last year by the combined staffs While most of the subjects studied are concerned with *tropical problems, there is much to interest medical men* in other parts of the world The medical profession cannot afford to neglect the many important contributions to its knowledge which are being made in India

THE CANCER ORGANIZATIONS OF AUSTRALIA.

The system adopted in Australia of confining the use of radium as far as possible to practitioners who have gained adequate experience under direction has been found to have justified itself in the opinion of the first Conference of the Cancer Organizations recently held at Canberra At each centre where radium is in use the cases receive the attention of a consultative group, which includes those physicians surgeons and other workers who are likely to be associated with the patient Changes in technique, moreover are not made without safeguards to ensure correct recording and accurate consideration of methods and results In a discussion of the possible avenues of research some of the aspects of lead therapy were mentioned by Dr W J Penfold, it is necessary, he considers to study the action of lead on normal tissues and to discover whether there are many individuals in whom there is less toxic action of lead on the general tissues than on the local growth In a large number of patients this is not the case, and lead therapy has been abandoned in Queensland, in spite of one case of ovarian cancer which is doing well two years after treatment with lead At the Commonwealth Serum Laboratories Melbourne, researches are being made into the metabolism of the Twort alveolar carcinoma of the mouse which indicate that it falls into line with the mouse, rat, chicken, and

[1] Annual Report of the Calcutta School of Tropical Medicine Institute of Hygiene and the Carmichael Hospital for Tropical Diseases 1929. Calcutta Bengal Government Press. 1930.

human malignant tumours investigated by Warburg Dr H G Chapman referred to attempts which are being made by the Cancer Research Committee of Sydney University to immunize persons against tumours—notably against melanotic sarcomata It is not expected that a biological immunity can be produced against the proteins of the growth, but it does not seem impossible that a chemical immunization may be obtained The method used is to grind up the tumour cells, immediately upon removal, with sand and salt solution the mixture is then centrifuged and the extract returned to the patient by intramuscular injection No results of this treatment appear to have been quoted at the conference In discussing the value of various forms of treatment, Dr E H Molesworth of Sydney insisted strongly on the importance of the pathological study of all tumours that are to be treated with radium, and on the determination of their finer structure, the special characteristics of their cells, and their infiltrating activity Upon these findings should depend the line of treatment adopted and the extent of the area treated It would then become possible to group tumours according to their radio-sensitiveness—a characteristic almost always the reverse of their suitability for operation He is strongly of the opinion that shorter wave-lengths exercise no selective action on tumour cells, the intense effect of embedded radium is localized, owing to the rapidity with which the intensity of its radiation fades as it leaves its source of origin To take an example, although it would be possible to obtain the same dosage with deep x rays to the uterus as with embedded radium, the effects would be more widely distributed, and would involve the bladder and bowels, so that the value of radium lies not in the penetrating powers of its rays, but on their rapid absorption as they leave the source If the theory of selective action of the shorter wave-lengths is abandoned, the matter has an economic importance, since it is cheaper to use the deep x-ray tube than a radium bomb at a distance of 20 or even 10 cm from the skin, in addition, the danger to operators is considerably lessened by the use of the x-ray tube The remarkable prevalence of pre-cancerous and cancerous lesions in the skin in Queensland is to be the subject of an investigation by Dr J V Duhig director of the Brisbane and South Coast Hospitals Laboratory It is hoped that his research will determine what effect if any, sunlight has on the genesis of cancer of the skin especially in white persons living in tropical or subtropical climates The histological range of variation in hyperplasia of the skin with a malignant tendency is very wide and clinical diagnosis is not reliable

INTERNATIONAL LEAGUE AGAINST RHEUMATISM

The second congress of the International League Against Rheumatism was held from September 18th to 22nd in Belgium and Holland, under the joint chairmanship of the President, Dr R Fortescue Fox, with Dr N M Josephus Jitta, President of the Dutch Society, Professor Labbe (Paris), and Professor Graeff (Hamburg), following the Fifth International Congress on Physical Treatment at Liege Both congresses were largely attended by representatives of fourteen countries, including many from Great Britain At a joint sitting resolutions were unanimously passed calling upon the medical faculties in all countries to press for the inclusion of a course of instruction in physical treatment (theoretical and practical) in the curriculum of medical studies The chief topic discussed was "Disorders of the circulation in the skin in chronic rheumatic diseases" In an introductory paper Professor Iunedei (Florence) described a method of recording skin temperatures and of examining the circulation in the skin—vasomotility, permeability, etc Professor B Prusik (Prague) read a paper on cutaneous capillaroscopy and the Congestion Test Dr J van Breemen (Amsterdam) contributed a short report on micro-capillary appearances and low skin temperatures in rheumatic cases, and Dr Foged (Copenhagen) dealt with the general study of skin temperatures and circulation Other papers, out of a total of sixty communications, related to the pathogeny of rheumatism (Professor Kontchalovski of Moscow), the analysis of the gaseous constituents of venous and arterial blood in rheumatism (Dr Pap Lagos of Budapest), muscular rheumatism (Professor Barany of Upsala), osteoarthritis and vasomotor disturbances (Dr Kahlmeter of Stockholm), protemotherapy (Dr Brabant of Brussels and Dr Besse of Geneva) calcaemia (Dr M P Weil of Paris), and the social and philanthropic work of the league In Brussels Dr Gunzburg professor of physical treatment in the university, gave a demonstration of cases in the physical department of the Brugman Hospital, differing diagnoses and nomenclature being especially studied Another series of demonstrations and discussions followed at the Clinic for Physical Treatment in Amsterdam, directed by Dr J van Breemen Both at the Brugman Hospital and in Amsterdam it is understood that plans are being prepared for erecting a larger clinic for rheumatic diseases, with beds and facilities for study and teaching At the meeting of the council and national representatives held in Amsterdam it was agreed to divide the work of the league into three sections (1) pathological, including etiology and clinical study, (2) therapeutic, and (3) social The connexion between rheumatism and housing was discussed at a public meeting in the Colonial Institute, Dr Fox expressing gratification that England and Holland had been associated in the initiation of a movement of healing which in the course of years might perhaps, like Van Tromp's broom, sweep the seas of rheumatism

CONTROL OF DANGEROUS DRUGS

The hydra-headed traffic in opium and other narcotics (writes our Geneva correspondent) has again been the subject of protracted discussions at the meetings of the Fifth Committee, the committee which deals with social questions The outcome is a request to the Assembly—which will be considered by the Assembly before it rises in the early days of October—to call a conference for the limitation of the manufacture of dangerous drugs This conference will, if the Assembly agrees, be held in Geneva in May next, and all States, whether members or non-members of the League, will be invited to attend Mrs Mary Hamilton, M P, gave some information concerning the procedure suggested by the British Government for the preparatory work This includes first of all, a conference of manufacturing countries (France, Germany, Switzerland, Netherlands, India, Japan, United States, Italy, Russia, and Turkey), at which the problem of distribution of supplies to be manufactured for the legitimate trade would be settled, in January the Advisory Committee on opium, on the basis of this preliminary conference, would prepare a draft convention, and the general conference in May, consisting of representatives of manufacturing countries, consuming countries, and countries growing raw materials, would draw up the final convention on the limitation of manufacture As stated, the Fifth Committee has decided to ask for the large general conference in May next, but it is not clear yet whether the preparatory programme suggested by the British Government is acceptable to the other delegates Some interesting information was given to the committee by the representatives of opium-producing countries Sir Ali Khan, a member of the Indian Legislative Assembly, said that since 1925 special efforts had been made in India to reduce

the cultivation of opium The exports of raw opium had been annually reduced by 10 per cent, and from 1935 no opium would be exported from India, except for medical and scientific purposes India would shortly create a central information office for the purpose of combating more effectively the abuse of narcotics in that country The Indian delegate urged that the League should make an appeal to the Turkish Government for efficient co-operation in the suppression of illicit traffic According to his statement, factories in Turkey for the production of narcotic drugs have recently been developed, and it is feared that the output of these factories may be used for illicit purposes Dr Chao-Chu Wu, the Chinese Minister at Washington, declared that the general picture given of the opium evil in China was too dark Stringent measures, he said, had been passed during the last twelve months by the National Government of China China, however, he added, was prevented from centralizing its police control, owing to the situation created by extra-territorial rights In illustrating the great danger for his people from the illicit use of narcotics—a greater danger, to his mind, than that arising out of the opium problem—the Chinese delegate said that the situation reminded him of the story of the man who fought the tiger at his front door while the wolf entered at the back He took a different view from the Indian delegate with regard to the situation in Turkey Although new factories had been established on Turkish soil, the capital for such enterprises came from outside Turkey Hussein Khan Ala, the Persian Minister in Paris, referred to the efforts made by his Government to complete its monopoly of the production of opium so as to be in a position to ratify the opium convention in the near future He said that the great economic importance for Persia of her opium production made it impossible for her to reduce it very suddenly With regard to illicit traffic in Persian opium, he declared that the vessels smuggling opium in the Persian Gulf flew foreign flags, and were not under the jurisdiction of his Government He hoped that Persia would be able to make arrangements with foreign Governments to find a lawful market for Persian opium, which would greatly help to put an end to the illicit traffic M Papadatos, an Under Secretary of State for Greece, said that while, five years ago, 80 per cent of the opium coming from Yugoslavia passed through the port of Salonica, in 1930 this export had been entirely stopped, thanks to the severe control exercised by the Greek authorities, and the rigorous system of issuing export certificates The production of opium in Greece, which had been 2,000 kilos in 1925, had fallen to little more than one-tenth that amount and a recent decree had established a State monopoly for narcotics, with severe penalties for infringement Mrs Hamilton, again putting forward the British point of view, suggested that the rapporteur in his final report to the Assembly, should not draw too dark a picture of the present situation In her view there was no reason for pessimism so far as the League's work was concerned The League had designed useful machinery in the fight against opium and the drug evil and if the desired results were not obtained it was due to the non-use by Governments of the machinery of the League In a similar strain spoke Mlle Hélène Vacaresco the remarkable Rumanian woman, out of an experience of ten years on the Social Questions Committee It was not any backwardness on the part of the League she said it was the great difficulty of overcoming the indifference of public opinion which accounted for the present position Mrs Hamilton added that when the West had done its duty with regard to narcotics it would be time to make a strong appeal to the supplying countries to join in the general effort to do away with the shameful abuse of opium and other dangerous drugs

INTERNATIONAL HOSPITAL CONGRESS

The first International Hospital Congress was held at Atlantic City, New Jersey, in June 1929, and a printed account of the proceedings has now been issued from the executive committee's office (2, Avenue Velasquez Paris) in a book of 390 pages The meeting opened under the best auspices, with messages of good will from President Hoover, and from the Prince of Wales (as Patron of the British Hospitals Association), the King of the Belgians, and the French Minister of Health Great Britain and Canada were well represented, and Australia, New Zealand, and South Africa each sent a delegate All the arrangements were in the hands of a special committee of the American Hospital Association, whose annual convention followed the congress, the two events being welded together so as to form a continuous week of study and social intercourse The introductory papers and debates are fully reported in the volume of proceedings Among the subjects discussed were the economic aspects of hospital planning and administration, the respective fields of public and private hospital work, accommodation for persons suffering from mental and chronic diseases, the development of hospital care and treatment for patients with mental disease, and the setting up of a central organization for the hospitals of all countries to assist in development of service to the sick on an international basis The main outcome of the congress, apart from the exchange of views and experiences, was the setting up of a provisional international hospital committee, whose members undertook to do their utmost to bring about the formation of regional and national hospital associations and their affiliation with the proposed central body It was resolved that the next congress should be held in Vienna from June 8th to 13th, 1931, preceded by visits to British, Danish, and German hospitals, and followed by a visit to Budapest The membership fee, for attendance and receipt of publications, is £1, which should be sent to Professor Tandler, Chief of the Welfare and Health Service of the city, 9, Rathausstrasse, Vienna

ROYAL SOCIETY OF MEDICINE

The officers of the Royal Society of Medicine have decided to continue the holding of special discussions during the session 1930–31 The following subjects have been chosen for joint discussions between two or more Sections the dates to be settled later and announced on the Society's diary card (1) vascular tumours of the brain and spinal cord (2) mental symptoms associated with cerebral tumours (3) medical indications for premature termination of pregnancy, (4) adaptation of European women and children to tropical climates, (5) scabies and ringworm as transmissible between animals and man, (6) indications for and value of the intravenous use of germicides The annual dinner of the Society will be held at the May Fair Hotel on Thursday, November 20th, at 7.30 p.m., with the president, Dr T Watts Eden, in the chair

---

The Long Fox Memorial Lecture will be delivered by Professor J A Nixon, M.D. in the Physiological Lecture Theatre of the University of Bristol on Tuesday October 28th, at 5.15 p.m. the subject will be the influence of food on the production and prevention of disease

---

The Semon Lecture entitled Some Observations on Semon's Law' (derived from evidence of comparative anatomy and physiology) will be delivered by Mr V E Negus, F.R.C.S., in the Barnes Hall of the Royal Society of Medicine, 1, Wimpole Street, on Thursday, November 6th, at 5 p.m.

Opening of the Winter Session.

WESTMINSTER HOSPITAL

ADDRESS BY DR SCOTT LIDGETT

At Westminster Hospital Medical School the inaugural address of the new winter session was given on October 1st by the Rev J Scott Lidgett, D D, Vice-Chancellor of the University of London The chair was taken by Mr Walter G Spencer, vice-president of the hospital and consulting surgeon

Dr Scott Lidgett said that it was not for him to discuss the history, the progress, or the present position of the art of medicine, or to advise medical students as to the prosecution of their studies He had the honour, however, as its Vice-Chancellor, to represent the University of London, with which the Westminster Hospital Medical School was so closely associated He had had a good deal to do with public affairs for many years, and had worked in close co-operation with medical men in the University, on a very important Royal Commission, in various branches of local administration, and in numerous activities of voluntary philanthropy He might perhaps, therefore, speak without presumption on the subject of the medical school, the university, and the State In his judgement each of these three must respect the autonomy of the others Each must respect the province of the others and not attempt to encroach upon their self-government and initiative Yet the efficiency of each would be protected by ever closer co-operation between all three, and this co-operation was required if the welfare of the community as a whole was to be maintained The need of such co-operation must constantly bring all three into common counsel, not only in regard to the co-ordination of practical arrangements, but also in regard to the ever-growing financial needs and the common requirements of medical training, local education, and public service Financial needs were bringing the three great interests ever closer together at a time when the standard of efficiency was being raised, when immense fields of research demanded exploration, and when greatly increased practical calls were made upon medical skill and scientific knowledge The medical school naturally turned to the university for financial assistance in maintaining its activities and developing its plans, while the university looked not only to the generosity of enlightened citizens, but to the State and to public authorities for the means of discharging its growing responsibilities In return for this financial assistance it was the duty both of the medical school and of the university so to repay the State by the quantity and quality of their services as to make the generous consideration of their needs amply worth while, and to promote in the long run even economy in the State by the lightening of burdens which were in large part due to ignorance and neglect The establishment of such common counsel was leading to a great measure of interpenetration The Senate of the University had been enriched in knowledge and in wisdom by the eminent representatives of the medical profession who had served, and were serving, upon it, carrying back, it might be hoped, to the schools of medicine fuller understanding both of the policy of the University and of its profound sympathy with all the interests of medical education The State from time to time called distinguished professors and doctors of medicine to its counsels, and the great influence of medicine was shown by the fact that the old Local Government Board had now become the Ministry of Health The latest product of this co-operation and interpenetration was the scheme for the establishment of a post-graduate school of medicine, in the development and management of which the Government, the London County Council, the medical profession, and the Senate of the University were united It was hoped that by this co-operation practical steps might shortly be taken which, while respecting all that was at present being done in this direction, would co-ordinate the scattered agencies that already existed and, in partnership with them, bring about a consummation that would make London, with its unequalled field of observation and its potential means of research, the centre to which the medical profession throughout the country and throughout the Empire would turn with ever-increasing confidence and hope

Dr Scott Lidgett then passed to the underlying considerations which made this co-operation essential

"Medicine is an art It is primarily remedial It is concerned with healing and with healing with a view to realizing the ideal of individual and collective health It deals with what is from the standpoint of human life, efficiency, and happiness—the abnormal Its ever surer diagnosis and its ever extending research lead it to seek out not merely the symptoms, but the causes of what it regards as abnormal for the very reason that it is injurious Its practical treatment seeks in like manner not merely to remedy or alleviate the symptoms, but to ascertain and if possible, to eliminate their causes

"The University has as its very name suggests, universal science as its province It deals with all the realities of actual and factual existence From the standpoint of science, whatever is—that is to say, exists—must be treated in the first instance at least as normal All the phenomena of our cosmic existence are *there* and are organically related in the system and development of the world For example, the most deadly bacteria which are treated by medicine as the enemy, have their laws of nature in common with all the more pleasant and desirable phenomena of the universe They must therefore be studied thoroughly and dispassionately by biological science Adequate description, measurements, classification, and proximate explanation of the whole realm of existence lie within the realm of science, and therefore become a problem of the University

"The State stands for authority, for the government, to use Lincoln's historic phrase, 'of the people, by the people, for the people' In England at least, and until recent times, it was sought to limit the functions of the State to the interests of defence—external and internal The State was responsible for securing the safety and the freedom, within limits of its subjects It had to safeguard their continued being Yet, as experience has growingly shown, the being of the citizens of the State can only be maintained by ever increasing and more comprehensive endeavours to promote their well being Even the Englishman has become convinced, however reluctantly, of this necessity Hence the State, which began for the most part by being remedial, has become increasingly preventive and constructive in its constantly multiplying tasks It is therefore constrained to call to its aid all the available resources of science and art of knowledge, and of practical skill For the furtherance of its work it must turn ever more constantly to the outstanding representatives and centres of Science and Medicine."

Hence the interdependence of the medical school representing the art of Medicine, of the university representing Science, and of the State representing the authoritative and constructive government of the well-being of the people Medicine as an art was dependent upon the whole range of the sciences Primarily, of course, it must needs have regard to the sciences of physiology and biology Yet the study of these led back to that of chemistry and, more remotely, that of physics Nor could psychology be ignored, for in practice they were constrained to recognize the apparent influence of the mind, the emotions, and the will upon the bodily organs All these were of primary importance, but, in the relations of medicine to public life and to the State, medical jurisprudence and even other subjects of science and political science were being brought within the orbit of medical education Moreover, in the background the comprehensive subject of logic as training the students' reason to adopt truly scientific methods both of induction and of deduction On the outskirts lurked philosophy ready, if need be, to be called in Hence, it might be affirmed that, within practical limits, the wider and more thorough the scientific knowledge of the medical student became, the stronger background and the more effective instrument he would have for carrying on his remedial art Both Medicine and Science in this close interrelation were indispensable to the State in its efforts to establish the conditions of being, and therefore of well-being The State was becoming more and more constructive, and, in the true sense of the word, reforming It had to secure the co-operation of all people of good will in the great enterprise of a continuous

refashioning of our collective life in order to realize the possibilities and to correct the incidental drawbacks attendant upon human evolution As the State became constructive it cast the light of its great ideal over Medicine and Science Medicine became increasingly not merely remedial but preventive It treated the establishment of the conditions of health as the best prophylactic against disease Science placed the entire range of its knowledge at the disposal both of Medicine and of the State for this great positive and constructive endeavour On the other hand, the State was ever increasingly compelled to call in the assistance of Medicine and Science in national and local administration in order to take account of and deal with the whole range of human environment A transforming partnership of Medicine, Science, and the State was being brought about by their hitherto somewhat haphazard co-operation

What practical bearing, it may be asked, has all this upon the course and equipment of a medical student? The answer is simple though the attainment is arduous The medical practitioner must not only equip himself with adequate knowledge but must train and discipline himself to certain mental habitudes which have underlying moral conditions Human sympathy it need hardly be said is the foremost requirement that is involved A spirit of close patient and comprehensive observation must be cultivated The ever growing treasures of past experience handed down by tradition through teachers must be gathered up by the medical student verified, and used in his practice and eventually enlarged by his personal reaction to it Promptitude resourcefulness and dexterity are essential Constant vigilance and thoroughness are indispensable If these are the qualities that are called out and exercised by strictly medical training adequate scientific knowledge and a scientific outlook will bring breadth and a comprehensive vision accompanied by grasp of the conditions that are involved and command over the resources that are available

The sense of obligation to the State will develop a truly social aim a spirit of confident, though cautious, venture, and a disposition to seek organized co-operation in the service of public health All this involves intense and patient human sympathy and the highest consecration which subordinates the desire of individual advancement, however legitimate, to the great social end of the well being of the community that must become increasingly the ideal and inspiration of the medical man

ST GEORGE'S HOSPITAL.

ADDRESS BY LORD RIDDELL

AT the prize distribution to students of St George's Hospital Medical School on October 1st, Lord RIDDELL gave an address entitled "Some things that matter for doctors from a layman's point of view"

Lord Riddell first touched on the relationship between medical profession and public He said that the intelligent layman viewed with amazement and anxiety existing conditions regarding panel practice and the medical services generally The panel doctor was a sort of medical slave, employed, or at any rate paid, by commercial or semi-commercial institutions He must prescribe in accordance with certain rules If these rules were transgressed he was subject to serious fines and other penalties He was also subject to penalties if he were too free in granting certificates entitling patients to disablement allowances On the other hand, the less he did for his patients the easier time he had Except in cases of gross negligence there was no penalty for under prescribing or inattention Most of the insurance doctor's serious cases and a good many that were not serious, were passed on to or drafted into the out-patient departments of the voluntary hospitals The twelve London teaching hospitals alone treated every day about 12 000 out-patients a large proportion of whom were on the panel So great had the strain become upon some of these institutions that they had been compelled to require payment of a registration fee by out-patients It would be interesting to discover how many of the fourteen million panel patients were treated largely at the expense of the charitable public, and for what diseases Perhaps they would then find out what the panel patient got or what it was possible for him to get, for the 9s per annum paid to his doctor, plus the £10 16s 8d per annum per 100 patients allowed for drugs It was certain that, but for the voluntary hospitals, the panel system would very soon break down

Turning to the relation between doctor and patient Lord Riddell said that the public judged by results Unfriendly critics of popular medical favourites might allege that their successes were due to luck, not to skill This was futile criticism mankind had always had confidence in lucky people When the Romans had to choose between two generals, the senators said, "So-and-so is the better strategist But So-and-so is loved by the gods, therefore we shall appoint him" Nevertheless it was dangerous to trust to a lucky star Success depended on knowledge and the art of applying it, a reputation for skill was a valuable and enduring asset With some diffidence he proposed to say a few words about medical education from a layman's point of view First, he would suggest that notwithstanding the wonderful facilities for diagnosis provided by pathologists, biochemists, radiologists and cardiographers, the searching medical eye was still the most important weapon in the doctor's armoury Therefore every student should cultivate his powers of observation Secondly, the intelligent laity viewed with some apprehension the tendency to treat the human body as a departmental store Most organs had their own band of specialists It seemed to the thoughtful layman that the medical student at any rate should regard the human body as an entity, "many members but one body" Thirdly, a clear, concise method of expression should be cultivated for written communications President Wilson was a master of this sort of style, his father insisted, when he was a boy, on his deleting every redundant word from what he wrote It was amusing to practise this art, and astounding to see how much could be excised Fourthly, sooner or later most doctors found themselves in the witness box, therefore it was desirable for the student to pay some attention to the giving of evidence There were a few maxims that might well be remembered The witness should be prepared with his facts and technical information When possible he should answer "Yes" or "No" He should not fence with the judge or counsel, but give his answers in a clear, direct fashion He should keep his temper, and be genial and courteous under cross-examination He should avoid using technical words when he could substitute language readily understandable by judge and jury Fifthly, continuity was a great asset The man who day in and day out did his work to the best of his ability, never turning aside because he was weary, bored, or unsuccessful, was certain to make an ultimate success Furthermore, it was surprising how constant application would make the dullest subject interesting A knowledge of statistics, charts, and graphs was important A doctor should know how to construct these modern signposts But the critical spirit should be well developed, together with adequate analytical methods Statistics put forward by fanatics and enthusiasts should always be carefully scrutinized As an instance of the need for caution Lord Riddell mentioned the maternal mortality statistics that so frequently figured in the press

We are told by a well meaning, but ill informed group of ladies that our maternal death rate is much worse than the rates in certain foreign countries The truth is that the statistics cannot possibly be compared as each country adopts an entirely different method of making them up Even our own figure, 4 3 per thousand, demands a good deal of investigation This average is due in a great measure to the high death rate in a few districts, such as Wales where the rate is 6 1 per thousand and to the high rate in emergency cases at certain institutions where the figure is sometimes 8 per thousand, due to the fact that the patients have been interfered with by abortioners, who have thus rendered them liable to puerperal diseases In the City of Bradford (1921-23) for example, out of 125 deaths no fewer than 37 were associated with miscarriage or abortion Furthermore the death rate among unmarried mothers is very high due to maltention etc. On the other hand at the East End Maternity Hospital, London 17,525 cases were attended (1921-23) with only 12 deaths or 0 68 per 1 000 I am not suggesting that our midwifery arrangements do not require improvement I only mention these facts to show that general percentages are often misleading If abnormal cases were excluded from our maternity statistics they would present a very different appearance '

Another important thing was the doctor's manner—important both as a therapeutic agent and as a means of securing practice One thing was certain, superciliousness was fatal Some people had natural charm, or the gift of inspiring confidence, but manner was largely also a matter of training The cultivation of simple courtesy was a most important part of medical training Another thing that mattered was the disclosure by the doctor to the patient of medical information From time immemorial doctors had been in the habit of shrouding themselves with a sort of halo of mystery In an irreverent and inquiring age, when even the most sacred haloes had been snatched off, the medical halo had not escaped public attention The educated man or woman wanted to know what ailed him or her, more or less what the medical adviser proposed to do, and what course the disease was likely to take In short, the patient wanted particulars of the diagnosis, treatment, and prognosis In these days unwillingness on the part of the doctor to disclose these particulars was often regarded as evidence of ignorance Needless to say, however, much discretion was necessary in the patient's interest It might be better to be thought ignorant than to damp a patient's spirits by the communication of unpleasant facts In no professional calling was tact more necessary But an elaborate tactician who prided himself on his tactfulness was usually a dismal failure Real tact, like good manners, was unobtrusive This characteristic depended on the art of organizing the day properly A good organizer could make the most of himself and his time, whereas the muddler was always late and always driven Finally, optimism, geniality, and a sense of humour were invaluable assets to a doctor

Nova et Vetera.

DOCTORS BILLS

Under this somewhat crude title a letter recently appeared in the *Times*, the writer of which complained of the lack of details in medical accounts rendered He, or she (for the signature consists of initials only), thinks that every patient is doubtful whether he has been fairly dealt with It was not ever thus In the eighteenth century the accounts of surgeons and apothecaries were full of details, and a long bill" was a physical fact and not a mere manner of speaking As long as advice was not charged for and the only items of cost were for drugs supplied, the custom of retail trade prevailed, but when the apothecary became by Act of Parliament a medical practitioner (if not, like the attorney, a gentleman), he seems to have felt the ways of the shop degrading, and he went one better than the lawyer and sent in his claim for a lump sum for "attendance," and only gave dates and other details when they were asked for An example of the old custom will be found in "A Doctor's Bill of 1824," published in this *Journal* on June 28th, 1930 (p 1190) In this bill of Mr William Burgess of Lostwithiel, very full particulars of drugs supplied and attendance rendered, with the dates, are given

Through the kindness of Dr Cyril Helm of Great Horkesley, Essex, we have now before us a much earlier bill, rendered by Mr William Fairclough "to the Parish of Little Horkesley," for attendance on, and drugs supplied to, Mary Hardy at West Bergholt There is no address on the bill, which is dated 1771, but a reference to the "Medical Register" for the years 1779, 1780, and 1783 (the only years for which that early directory is extant) shows that a Mr William Fairclough practised at Nayland, just over the border in Suffolk West Bergholt, Nayland, and the Horkesleys, Great and Little, are all within a circle of about two or three miles diameter on the Essex-Suffolk border What the population of Nayland was in those days we do not know, in 1906 it was about 1,500, but in 1779 it supported three medical men, Messrs Fairclough, Tomkins, and Leak whose practices no doubt covered a large radius Dr Helm justly remarks that the charges seem high for the period, and, we would add, for a parish patient The attendance extended from June 11th to August 2nd, and the total is £3 16s 6d Fifteen of the twenty-eight items are for journeys, and the remainder are mostly for decoction of bark, so that it seems possible that the case was one of ague A journey was charged at 2s 6d, and a "Decoction of the Bark, containing a Quart, 3s 6d" This quantity only lasted the patient from three to six days, so that a fair amount of cinchona must have been absorbed

It would seem that there was no salaried medical attendant under contract to attend the poor of Little Horkesley at that time, or else we should not have had this bill It is, however, well known that long before 1771 various parish overseers made contracts with surgeons and apothecaries for attendance on the sick poor In that delightful and learned work the *History of Hitchin*, by Mr Reginald Hine, there are records of several such contracts in that old royal town of Hertfordshire "In 1711 Joseph Thompson agrees with the townsmen of Hitchin, for a consideration of £3, 'to use his utmost endeavour in curing broken bones, dislocations, strains tumors, swellings, fistula, gout ulcers, chancres, and all other wounds or thinges whatsoever that belong to a surgeon', while at a price just double that of the surgeon, the apothecary, Thomas Ward, covenants to 'take care of all the poor and use his best skill in cureing all fevers, smallpoxes, and all other distempers that belong to a physician' On one of the later contracts, as if to justify the need of them, this couplet is endorsed

'Because that word and faithe with no degree will stande "
Therefor the Lawyer saithe, take writing of their hande "

There is much else in Mr Hine's chapter on the poor, in his first volume, of interest to the medical reader He concludes thus

"Looking back over these merciful interventions, one feels that the parish doctors were in act and deed the friends of the poor, for if by mischance they killed off a few of the King's sick subjects by their medicines they saved many lives by foresight and sympathy in times of famine"

To turn again to Mr Fairclough and his bill There is no indication of its having been paid, so that perhaps his charges were above the usual rate and he may have been beaten down by the overseers of the parish of Little Horkesley, and did not, after all, receive the sum of £3 16s 6d

Ireland.

Campaign Against Tuberculosis

The Village Settlement in connexion with Peamount Sanatorium, County Dublin, was recently opened by Mr James McNeil, Governor-General of the Irish Free State, and the Women's National Health Association is to be congratulated on the successful conclusion of its endeavours in this respect In 1906 the association commenced its efforts to combat the ravages of tuberculosis in Ireland, the death rate was then 2·6 per 1,000 of the people, nearly twice as high as that in England and Wales, but by means of propaganda and the establishment of sanatoriums in various parts of the country the association succeeded in limiting the extent of the disease The death rate decreased consistently until 1914, when war conditions interrupted the fall, the rate again dropped during 1918, 1919, and 1920 Even so, no fewer than 50,000 persons in the Free State died from the disease during the period 1918–27

The late Sir William Thompson, Registrar-General for Ireland for twenty years, was from the first a strong supporter of the association In the course of his investigations into the disease he visited the Papworth Settlement at Cambridge, and there saw the results achieved by Dr Varrier-Jones He brought the system under the notice of the Peamount committee, who were already anxious as to the fate of patients who, after a course of sanatorium treatment, were compelled to return to unsuitable conditions Having considered the matter, the committee felt that the establishment at Peamount of a village settlement on the lines of Papworth was the best solution

of the problems presented in the eradication of tuberculosis in the Free State—the procuring of employment which would enable the patients to enjoy plenty of fresh air, the kind of work for which they were suited the rest periods needed and the food which their impaired constitutions required Since 1918 Papworth's industries have sold more than £735 000 worth of goods manufactured by tuberculous employees and have paid £135,000 in wages The turnover in 1918 was £400 in 1929 it was £65,000 The village settlement at Peamount is a memorial to the late Sir William Thompson, dependent for the whole of its capital upon public donations, its rate of development will be governed by the orders it receives for the goods it produces which include all kinds of portable wooden buildings garages, bungalows, and poultry houses The Governor General explained how the settlement had been founded on the Papworth institution and added that it was now in a position to train tuberculous patients with a view to settlement The Peamount institution has not however merely adopted the Papworth general policy and methods though it had been built up under the personal supervision of Dr Varrier-Jones, confidence existed that the settlement which is already on its feet will with his further help stride out soon on its own account The advantages of settlement treatment to the working man and his family are now recognized The tuberculous patient is given the work he can do under proper conditions and at a proper wage His family and friends are saved from infection and the risk of infecting the community is lessened It was well known what poor men or women had to suffer, and how their whole outlook on life was darkened when protracted illness with incapacity to do regular work came upon them The settlement would hasten the cure of tuberculous patients, and hold out to them a continuing hope From being broken and hopeless they could be made healthy and self supporting

Sir Conway Dwyer, I R C S I, proposing a vote of thanks to the Governor General, said that the essential object of the industrial settlement was to render permanent as far as possible the results of sanatorium treatment As everyone knew the disquieting factor in this treatment was the tendency to relapse after returning to the conditions and environment in which the disease had been contracted It was to eliminate that result that what he might call shortly the Papworth system had been organized The patients at the conclusion of the sanatorium treatment did not go home They were provided with a new home under ideal conditions, and resumed their occupations or were taught a new trade, their families resided in the settlement with them, and could earn enough, or nearly enough, to maintain themselves Dr Varrier-Jones emphasized the importance of the scheme of treatment in that it took away from the disabled that feeling of inferiority, and gave them an opportunity of looking after themselves in a suitable environment The new workshop at Peamount was ten times as large as the first one in Papworth, which was erected ten years ago Without such institutions there would be an ever increasing number of men and women who would be a drag on the State and on private charity, but, thanks to such settlements the disabled people would become self-supporting The only thing they could not do was to pay dividends on the capital required for the workshops, for that the help of the charitably disposed was needed, and when the capital had been supplied the disabled men would be able to earn their own living The goods produced by the settlement were sold on merit at the correct price and they gave value for money The more of these goods that were sold the more people could be treated, and the general community be saved from infection Lady Aberdeen asking the Governor-General to start the machinery in the workshop said that ever since Peamount Sanatorium had been opened in 1912 the Women's National Health Association had cherished a dream of being able to devise some plan whereby patients who improved in health should be put in a position to earn their own living instead of returning to conditions which would almost certainly revive the trouble, and make them again dependent on State assistance They would see to-day this dream beginning to be realized She hoped that the starting up of the machinery of that little workshop would bring in a new era in the treatment of tuberculous patients in Ireland and would lead to the same success as that which had been achieved under Dr Varrier-Jones at Papworth

Proposed Sweepstake in Aid of Cork Hospitals

A deputation of the governors of Cork hospitals waited recently on the Minister for Justice to obtain his sanction for the starting of a sweepstake in favour of some of the Cork hospitals The Minister for Justice replied that while he did not altogether favour the project, he had a perfectly open mind on the subject Before he could give his sanction under the Hospitals Sweepstakes Act to any sweep takes outside that already being promoted in aid of the Dublin hospitals, a very strong case would have to be presented It seemed to him that the Cork hospitals would stand to gain more by taking part in the Dublin sweepstakes than by forming a separate one Generally he was not in favour of having rival sweepstakes organized If a good case were submitted he would consider it, but a strong case would be necessary to ensure the obtaining of a licence He had not given any decision to the deputation from Cork, since the matter had only been discussed generally

Scotland

Scottish Board of Control

THE General Board of Control for Scotland, at the outset of its recently published sixteenth annual report,[1] records its high appreciation of the way in which the local authorities, now no longer in existence, have discharged their onerous duties, of the progressive and enlightened manner in which successive reforms and new methods or treatment have been adopted, and of the human sympathy which their members, collectively and individually, have always shown to the unfortunate patients under their charge A considerable part of the report is devoted to occupational therapy It is recalled that the Royal Commission of 1857 suggested that there are few better curative agents in the treatment of insanity than agricultural labour when combined with an adequate diet" In accordance with these opinions the Board has encouraged the acquisition by institutions of farm and garden ground, and has generally recommended a minimum of one acre for each male patient No special cognizance has hitherto been taken of the fact that there is scope for the employment of women patients in farm and garden work, provided that suitable instructresses are engaged to teach and supervise them Such outdoor occupation would include light garden work, tending poultry, and milking and would provide healthy exercise of much therapeutic value In encouraging the acquisition of land by asylum authorities the Board has had mainly in view the object of providing therapeutic occupation and recreation for patients It has never been intended that asylum farms and gardens should be run primarily as profit making concerns but most asylum farms not only pay rents, which cover the interest of money expended on their purchase but usually have a considerable balance of net profit to apply towards the reduction of the cost of the maintenance of their patients It may also be claimed that the farms and gardens furnish a more varied dietary and a better quality of food than would be obtained by purchase in the market There is another aspect of the matter to which the Board directs attention—namely the possibility of depositing on behalf of those patients in whom there is a prospect of early recovery some small remuneration based on their work in the hospital This policy would give new interest and life to their work, and would also ensure for them a certain security on their discharge Another part of the report deals with carriers" of infections such as enteric fever and dysentery A special department for housing the enteric fever carriers," which number thirteen, at the Govan District Asylum, is now in occupation Peference is also made to the special work done in one of the Glasgow

[1] Edinburgh H.M. Stationery Office. 1930. Cmd. 365. 2s. net.

asylums, where undulant fever was discovered, particularly among patients who had been doing farm work The Board has had under consideration the hours and general conditions of service of the nursing staff in Scottish asylums In commenting on the practice that prevails in France, where a definite eight-hour working day is laid down by law, it deprecates a too rigid application of this principle in a profession such as nursing, and points out that nurses in general and mental hospitals have not been included within the scope of the draft Convention of the International Labour Congress dealing with the question of a general eight-hour day for all workers At the beginning of the present year, exclusive of insane persons maintained at home by their natural guardians, there were 19,059 insane persons in Scotland of whom the Board had official cognizance This figure includes the inmates of training schools for imbecile children who have not been certified under the Mental Deficiency Act and of the criminal lunatic department of Perth prison The total number of patients admitted to establishments (excluding transfers) during 1929 was 3,173, which is 136 fewer than in the previous year The Board of Control has sent to the new authorities instructions relating to the working of the Mental Treatment Act, 1930 "Mental hospital" is to be substituted for "asylum", this is now a statutory requirement "Voluntary patient" is to be used instead of "voluntary boarder" The word "pauper" is forbidden in relation to any person of unsound mind, and is to be replaced by "rate-aided person" The word "lunatic" is eliminated except in relation to criminal lunatics and persons detained as lunatics outside Great Britain

Pinel Memorial in Edinburgh.

A bust of Philippe Pinel was unveiled on September 26th at the Jordanburn Hospital, Morningside Park, Edinburgh, by M de Fleuriau, the French Ambassador The Jordanburn Hospital was recently established for the treatment of early mental uncertified cases by the managers of the Royal Edinburgh Hospital for Mental and Nervous Diseases The preliminary meeting, before the unveiling of the bust, was held in the lecture hall of the hospital under the presidency of the Earl of Stair Mr T M. Gardiner, chairman of the board of managers of the Royal Hospital for Mental Diseases, in welcoming M de Fleuriau, pointed out that the foundation of the Royal Edinburgh Mental Hospital by Dr Andrew Duncan towards the end of the eighteenth century took place while Pinel was agitating in Paris for the more humane treatment of the insane Professor G M Robertson, physician superintendent of the hospital, said that after the termination of the Napoleonic wars young medical men from Edinburgh were attracted to Paris by the fame of its school Two of the most famous among them were Sir Robert Christison and Dr Andrew Combe, the physiologist and phrenologist These men attended the lectures on mental diseases delivered at the Salpêtrière by Esquirol, the friend and pupil of Pinel, and they met Pinel and heard all about his great reforms Twenty years later they were managers of the Edinburgh Asylum, about the time when it was decided to enlarge the institution The West House was then built, and a bust of Pinel was placed over the entrance archway This was the first memorial erected to the memory of Pinel and his work, for even in his native country a statue was not erected until 1885 The managers had now decided to commemorate the centenary of Pinel's death by placing a new bust in a prominent position It was sometimes difficult to fix the exact time for the starting-point of any great philanthropic movement, but there was no difficulty in dating the introduction of the humane treatment of the insane It was generally agreed that the movement began definitely in the year 1793, when Philippe Pinel struck off the chains of fifty-three insane patients at the Bicêtre Hospital in Paris This was the year during which Paris was passing through the tragic experiences of the September massacres and the execution of the king and queen Pinel's humane action had received sanction from Couthon, one of the most bloodthirsty ringleaders of the Reign of Terror The reforms of Pinel also included all possible measures for improving the condition of the insane, such as the provision for better housing, warm clothing, good food, and the comforts of life He also introduced more careful medical examination, and one of the first results was the discovery by his pupil Esquirol of the symptoms of the disease known as general paralysis of the insane, which might be regarded as the greatest discovery in mental medicine Three years after Pinel began his reforms the Quakers of York independently established "The Retreat" in that city, also managed on the most humane principles When the Edinburgh Asylum, proposed by Dr Andrew Duncan in 1780, was opened for the reception of patients in 1813, it was conducted on the lines laid down by William Tuke at York and by Pinel in Paris Since then progress had been continuous In the course of his address, M de Fleuriau said that this gathering was a recognition of the common work of French and Scottish physicians and nurses united in the treatment of the terrible disease of insanity Philippe Pinel's work must be considered in the light of the eighteenth century He was born in 1745, and had been educated at Toulouse and Montpellier, leaving the university with the reputation of a very learned and able man with great personal charm Coming to Paris, he met many of the men who were playing a part in the movement out of which came the French Revolution This was a movement for the betterment of humanity and conditions of life in France, and questions of teaching, education, hospitals, and treatment of the insane were all under discussion When the Revolution broke out in 1789 many solutions of these questions had already been prepared, and the French revolutionary assemblies helped to initiate many reforms The fault of the revolutionaries had been that they sometimes went too fast in their desire to obtain immediate results Pinel had a long life, and in his later years he was one of the most celebrated professors of the Faculty of Medicine in Paris M de Fleuriau said he was very glad to have had the opportunity of expressing his respect for the memory of Pinel The company then adjourned to the courtyard of West House, where M de Fleuriau unveiled the bronze bust of Pinel, which had been draped with the French and Scottish flags The bust is a replica of one in the Academy of Medicine in Paris A wreath was placed on the memorial by the nation of the hospital, and Dr Hamilton Marr proposed a vote of thanks to M de Fleuriau, and Professor Patrick Geddes recited some verses that he had composed in honour of Pinel

Glasgow Health Exhibition

A housing and health exhibition was opened in Glasgow on September 24th by Mr Thomas Johnston, M P, Under Secretary of State for Scotland Lord Provost Kelly, who presided, said that the interest which the public took in such exhibitions was manifest from the success of those that had previously been held A special feature on the present occasion was the contrast in housing conditions shown by models of old and new houses In declaring the exhibition open Mr Johnston said that people were living healthier and happier lives now than their ancestors Although there were still epidemics, there were no such conditions as when James Melville in the sixteenth century rode through the streets of Edinburgh and found only three persons abroad, or when James VI ran zigzag about the country to escape the pest Many diseases had disappeared completely, such as typhus, malaria, and small-pox, while the diphtheria death rate had fallen in this century by one-half, and enteric fever was down to one-tenth of what it was thirty years ago Summer diarrhœa, too, was gone, owing perhaps to the coming of the motor car and the disappearance of the horse from the city The mortality rate of tuberculosis was one-half of what it was ten years ago The Scottish death rate from all causes had fallen between 1881 and 1921 from 19 30 to 13 56 Some diseases, however, such as cancer, rheumatism, whooping-cough, and the common cold, had not yet been eliminated, in regard to rheumatism we were no further advanced than in the days of Hippocrates, though we did recognize that every death from disease to-day was an unnatural and avoidable death There were many battle fronts in fighting disease, such as intemperance, venereal disease, smoke pollution, pestilential slums,

and adulterated food, but progress was being made. This exhibition marked an advance in the struggle against slums and against disease. He thought it was a disgrace that while £70,000 a year was being spent in Scotland on agricultural research and £20,000 on fishery research only £8,000 a year was being spent on research into diseases which afflicted the human being. In his opinion existing knowledge was not properly utilized for there had been an absence of combined work in hospitals. He trusted that the regional committees recently set up would mean that certain hospitals would be set apart for providing specialized service in particular diseases so that the latest fruits of research would be made generally available.

Glasgow Chair of Medical Paediatrics

The Board of Curators of Glasgow University, on September 25th, appointed Geoffrey Balmanno Fleming, M.D., F.R.F.P.S., to the Samson Gemmell chair of medical paediatrics in Glasgow University in succession to Dr. Leonard Findlay who recently resigned the professorship. Dr. Fleming is 48 years of age and after graduating B.A. at Cambridge in 1908 and M.B. in 1910 he took the degree of M.D. in 1914 and became a Fellow of the Royal Faculty of Physicians and Surgeons, Glasgow, in 1926. After holding various resident posts he studied in Vienna and later took up practice in Glasgow. He served throughout the war, retiring from the Territorial Service in 1920 with the rank of lieutenant-colonel. Since 1919 he has devoted his attention to paediatrics in the Sick Children's Hospital at Glasgow, where he was appointed assistant to Professor Findlay and later, Gow lecturer in the medical diseases of children at Glasgow University. Two years ago he became physician to the Sick Children's Hospital. He has made numerous contributions to current medicine.

Conference of Insurance Committees at Inverness

A two days' conference of the Scottish Association of Insurance Committees opened in the Town Hall, Inverness, on September 26th where about two hundred delegates from all parts of Scotland were welcomed by the provost and magistrates. Mr. A. A. Dick of Lanark county who presided, said that the question of extending and developing the medical service under the national insurance system was at present being discussed with great intensity and was nearing a climax. The British Medical Association had prepared a very carefully drafted scheme for a general medical service for the nation and this was so opportune that it was bound to play an important part in determining the future official attitude. The question now was whether the people of this country should be medically treated by whole-time medical officers appointed either by local authorities or by the State, or alternatively whether the present scheme of medical service under the Insurance Acts should be widened so as to bring everyone within its scope, thus retaining the right of free choice of doctor, which was the essential feature of the national insurance scheme. He was inclined to subscribe to the principle that the family doctor was the foundation of any complete and efficient medical service, and that as there was no real distinction between the preventive and curative branches of professional work every general practitioner should be associated with all health services. The passing of the old parish councils raised afresh and in an acute form, the question of the future provision of medical service for the poor. He submitted that if the national insurance system was to be extended local authorities through their public assistance committees might confer with local insurance committees and devise a method of contracting under the insurance system whereby domiciliary medical attendance might be provided for those for whom local authorities were responsible. This would do away with the present segregation of the poor as such, and would preserve for them the valued right of free choice of doctor. Under such an arrangement payment would be made by the local authority into the pool from which the local committee drew its funds. He was convinced that the whole arrangement could easily be brought into operation if both sides were agreed, and he was sure that permission would not be withheld by the Department of Health. Even if legislative authority were necessary, this would be of a simple character. Mr. Dick also pointed out that institutional treatment was an essential part of a complete medical service. In this connexion increased facilities, greater efficiency, and proper co-ordination of existing institutions were necessary and urgent. Many insured persons as well as others demanded, and were able and willing to pay, a reasonable charge for accommodation. The private hospital or nursing home did not meet this need to-day, for charges were often excessive and even extortionate. In any case there was room here for an improved nursing service which should be met in any scheme for general hospital accommodation. Private nursing institutions should also be subject to some kind of inspection and control as a safeguard against the exploitation of patients. They were told that the hospitals, both voluntary and council, were being used to an increasing extent by persons who would not and should not ask for charity, in the building of more hospitals provision should be made for patients who could pay and were willing to pay. A motion by Sir Henry Keith was carried to remit to the executive committee the consideration of the extension of domiciliary medical service with the object of making such service as comprehensive as possible. An address on the medical service in the Highlands and Islands was delivered by Dr. Shearer of the Department of Health for Scotland. He said that the improved conditions of medical practice in the Highlands and Islands had been of enormous benefit to the people. The provision of motor transport had made it possible to do in one day what had previously taken three or four days. Through the Highlands and Islands Medical Service Fund the poorer classes could get prompt and adequate medical attention and the nursing services were now better. The medical services in these districts had been transformed, and a nursing service, which was an incalculable boon, was being steadily improved and extended. He referred also to the establishment of specialist service and to the modernizing of the Northern Infirmary at Inverness. He expressed the opinion that if the problems of the Highland medical services had been treated sectionally progress would have come to an end but now all over the world in Kentucky, in Newfoundland, and in South Africa the ideas which had been worked out and tested in the Highlands of Scotland were being adopted and applied to cognate problems.

England and Wales.

After-care of Defectives in Birmingham.

THE report for the year 1929 of the Special Schools After Care Committee for the City of Birmingham contains an account of some of the defective persons who have become either partially or completely self supporting since going out into the world. Efforts have been made during the last three years to obtain information on the occupations commonly followed by defectives in the industrial life of the city and it has been found that the numbers doing remunerative work are the highest since the committee was established. As many as 1,295 males and 716 females are now in work, the wages of the men range from 2s. to £5 per week, and of the women from 2s. to £2. In several cases defectives have remained in the same employment since leaving school, one having held a post as a domestic servant for the last ten years, the committee's visitor reports that others are much improved and one is now attending an evening school. Occupations include engineering both skilled and automatic unskilled factory work, electro-plating, outdoor work, domestic service and the sewing trades. Bootmaking and carpentry are two of the trades taught in the special schools and it is of interest to note that fourteen are engaged in the boot trade and nineteen in different branches of carpentry. A number of children—namely 222 males and 177 females—have been excluded from special schools during the past five years by reason of mental or physical disability, these are children who, after a varying period in the schools failed to make any progress in education. Most of them remain

at home subsequently, but some of them attend occupation centres, others are eventually placed in institutions, and a few are able to find employment, though it is seldom long retained The percentage of defectives doing remunerative work has steadily increased since the inception of the committee, and now amounts to 47 per cent—a not unsatisfactory figure when the amount of general unemployment is considered A special investigation has been made into the family histories of former pupils of the Birmingham special schools who were known to have married or to have had children, 376 children are noted as born of fathers who had been certified as mentally defective, and 270 of mentally defective mothers Of 276 of these over the age of 5 years, fourteen are reported to be mentally or physically defective, and of the 370 below that age fourteen are said to be mentally subnormal or not in good health In the younger group it is still too early to make an accurate diagnosis in the greater number of cases, but most of the older children are attending ordinary elementary schools Delinquency among defectives is usually of a minor order, and in the records of the committee very few cases have been found which have been the subject of police court proceedings, the usual forms of delinquency noted are minor thefts, a tendency to wander, and, among the females, a liability to be victimized sexually More than seventy children attend the four occupation centres, where useful training is given to low-grade defectives who cannot profit by the instruction at the special schools

London Hospital Post-graduate Course

The annual post-graduate course for former students of the London Hospital will be held this year on the four days October 15th to 18th For each day, except the last, a full programme of lectures and demonstrations has been arranged On October 15th Dr Donald Hunter will lecture on vitamins Dr W J O'Donovan on the major skin infections of childhood, Mr Hugh Lett on the enlarged prostate, and Mr Hugh Cairns on the treatment of trigeminal neuralgia There will be demonstrations of cases treated by radium, surgical operations, and ward demonstrations during the afternoons, and Dr George Riddoch will discuss the diagnosis and treatment of Parkinsonism and will show cases On the second day Dr Maitland-Jones will lecture on some nutritional disorders in infants, Mr C B Goulden on injuries to the eye Mr Eardley Holland on some common obstetrical problems, Dr Russell Brain on some causes of pain in the leg and Dr O Leyton on diabetes Mr Victor Luck will hold an ante-natal clinic in the afternoon, and the annual dinner of the London Hospital will be held that evening, as already announced in these columns Lectures on the third day will be given by Dr T Lumsden on immunity in relation to malignant disease, Mr Alan Perry on infections of the hand, and Mr G E Nelgan on cystitis Mr Norman Patterson will demonstrate cases and specimens, Dr A E Clark-Kennedy will give a ward demonstration on dyspepsia, and Mr H S Souttar will deliver the Schorstein Memorial Lecture on radium in the service of surgery It is proposed that a demonstration by Dr Daly on methods of anaesthesia shall be held in the evening The course will conclude on Saturday morning with lectures by Dr G Vilvandre on some pitfalls in x-ray diagnosis, and Mr A J Walton on the present state of thyroid surgery Mr Russell Howard will conduct a ward demonstration In addition to the course here outlined, there will be operations in the theatres each afternoon from 1 30 onwards and demonstrations in the wards

Children's Sanatorium, Harpenden

The Children's Sanatorium at Harpenden, Herts, which was built in 1910 as a special branch of the National Children's Home and Orphanage, provides facilities for medical treatment along with the amenities of home and school life About seventy tuberculous children between the ages of 5 and 14 including those whose health has been seriously impaired by early privation and neglect, can be received in the present building, but larger accommodation is expected to be available at an early date in anticipation of fuller co-operation with local authorities The sanatorium is recognized by the Ministry of Health, the Ministry of Pensions, and the Board of Education, and possesses equipment for study and recreation all the year round Among its facilities are an open-air school, fitted with sliding panels and movable partitions, playgrounds, playing fields, and play-sheds for use in bad weather A number of revolving outdoor chalets have been erected in part of the surrounding gardens, where plots of land are cultivated by the children themselves Wide, open verandahs run round the whole of the frontage of the main building, which consists of two floors of wards, day rooms, a central dining-room, a consulting-room, and a surgery This building has been named Wakefield House, in recognition of the sympathy and generosity of Lord Wakefield of Hythe Particular attention is given to dietary, exercise, and to matters of personal hygiene The records of the sanatorium, to which Dr T N Kelynack is visiting physician, suggest that these natural methods of treatment result in a high percentage of success when they are applied systematically and at the right time

Correspondence.

INTERNATIONAL CO-OPERATION IN HEALTH
THE RHEUMATIC DISEASES

Sir,—Your welcome editorial on the health work of the League of Nations in the *Journal* of September 27th (p 536) clearly shows how much strength our medical art may derive from international co-operation, and also how great a contribution it is now in a position to make to the economic and social problems of the world Least of all the great vocations can the Medicine of the future be exclusive, insular or national May I add my small tribute to this newly acquired value, from a personal experience of ten years in rather active work in the field of physical medicine? I refer to the serious study of physical remedies in all civilized countries, which are in the first place especially the remedies of the health resort, and which, of course, find their ruling indications in the treatment of incipient and chronic disease

During the past five years a large number of workers in chronic rheumatic diseases have been organized as a small international league for combating these diseases Their first object, in the words of Miss Lawrence—speaking of the League of Nations organization—is "the study and collection of information" But in the case of rheumatism investigation must go hand in hand with a careful study of treatment, partly because the sick man cannot wait and partly because it has been shown that the close observation of large numbers of cases *under treatment* throws much light on the morbid process and quickly establishes a therapeutic differentiation

The health activities directed from Geneva have often, as you point out, led to rapid and most beneficial results In the case of rheumatism also, we believe that a wisely directed co-ordinated effort will be much more fruitful than any isolated efforts The constant international interchange that has been established between workers on rheumatism has already effected a much-needed understanding between sections of the medical profession The young cardiologist or bacteriologist, keen on his "scientific" work, has been brought into contact with other categories of fact, the contribution perhaps of much older students and clinicians *Pace* Mr Wilfred Trotter, they have learned that scientist and clinician are not mutually exclusive terms Both schools have during the past week studied together the disturbances of circulation and bodily heat which characterize the development of many rheumatic illnesses and which call aloud for investigation

It fell to me at the second rheumatism congress, just concluded, to lay before my colleagues at Liege the call to co-operation "How essentially similar are the problems which confront us all" In dealing with these sometimes baffling medical problems, with their serious economic and social aspects, co-operation is necessary all along the line, first between sections of the medical profession, then between ourselves and other organizations

concerned with social and economic welfare and lastly between nation with their own individual genius, experience and energy.—I am, etc.,

London, W.1, Sept. 23rd. R. LONTE CUT FOX

X-RAY AND DIATHERMY TREATMENT OF TONSILS

SIR,—There have been several letters in the *Journal* recently about the x-ray treatment of tonsils. As I had been using this method for some few years and probably treated over a thousand cases, my results may be of some use to readers. At the Rockefeller Institute for Medical Research in 1919 Drs. Witherbee, Murphy, Craig, Hussey and Stern treated forty-six patients from 31 to 45 years of age by x-rays. The result of the work showed that within one month of starting treatment no colonies of haemolytic streptococci or staphylococci could be found in tonsils in which before they had been present. My own results were not so good, so I supplemented the x-rays by one-minute exposure to the ultra-violet lamp, application of the high frequency electrode, and the use of a vaccine prepared from the organisms present in the tonsils.

With two treatments a week over two to three months I was able to get very good results. The tonsils shrank and became pale, and no secretion could be expressed from them. In about 90 per cent. of cases results were very satisfactory. A few resisted all treatment, and during the next four or five years a few returned with a recurrent infection. Patients who have had their tonsils treated, and find them years later, as bad as they were originally, feel very badly used. I therefore scrapped the method, and during the last three years have employed diathermy, using a unipolar method off a Schall machine. I mention this machine as I have not heard of any other by which this method can be applied. With a needle protruding a good quarter of an inch from a glass rod a tonsil can be dissected out, as with a knife, except that the operation is bloodless, or the needle can be entered to its full depth and moved slowly backwards and forwards across the tonsil, *cutting its way through and destroying all in contact with it*. Least reaction and discomfort is produced by doing half a tonsil at a sitting. The operation does not prevent the patient carrying on with his daily work, it can be applied to elderly folk with weak hearts as long as they are able to come to one's rooms. One can do as much or as little as one wishes, and there is no uncertainty as to how deep one is burning. Full current is used and only one electrode employed. Where x-ray treatment is used alone, even if good results are obtained the tonsils are bound to be reinfected in the presence of dental or naso-pharyngeal infection.

The fact that the tonsils of about 90 per cent. of people are infected does not mean that the condition is normal, and we do well to eliminate all sources of the streptococcal infection at present much harm is being done by removing tonsils and leaving nasal infections.—I am, etc.,

Melbourne, Victoria, Aug. 11th. SYDNEY PERN

SUCTION IN TONSILLECTOMY

SIR,—In your report of the proceedings in the Section of Anaesthesia of the British Medical Association Annual Meeting (*Journal*, September 27th, 1930) I have read with interest the reference made to the prevention of respiratory complications after tonsillectomy. It is surprising that no single anaesthetist has mentioned the value in this connexion of suction to prevent accumulation of mucus and blood in the air passages.

A very simple apparatus of low cost can be erected in any operating theatre whereby a *constant suction* can be maintained during operation. This consists of a modified Bunsen water pump attached through a suction bottle to a Yankauer tube. The tube can be manipulated by the anaesthetist and can most effectively be made to remove the blood from the site of operation. It can be kept free from clotted blood by dipping occasionally into a sterile solution of sodium citrate. Operation, particularly dissection in adults, are rendered comparatively simple as anaesthesia can be pushed with safety to full relaxation without fear of the inhalation of blood. Efficiency is greatly increased, as a full view of each step in the operation is obtained. Constant recourse to sponging is obviated, and bleeding points can, if necessary, be clamped with ease. The patient is allowed to regain his cough reflex before leaving the table.

I think it will be found that the dangers and complications of the operation are reduced to a minimum and the ease of operating increased a hundredfold.—I am, etc.,

Bedford, Sept. 23rd. C. A. METCALFE, M.A., M.B., B.Ch.

RADIUM TREATMENT OF RODENT ULCER

SIR,—During the last year I have treated a considerable number of rodent ulcers and have seen the resultant after-effects, which, in the majority of cases are in the form of a smooth scar. If unscreened applications were used, containing either radium element or radon, treatment for a few hours sufficed but it was found necessary to screen the surrounding healthy skin with lead, otherwise a burn developed. It however, tubes screened with 0·6 mm. of platinum were used, then treatment needed to be prolonged for six days and no protection of the surrounding skin was necessary.

The introduction of a platinum screen, with consequent filtration of the beta radiation necessitating a much longer exposure, is, I think, proof that the beta radiation is the effective agent in the treatment of rodent ulcers with unscreened tubes, while the necessity for protecting the surrounding skin with this type of treatment shows that these radiations possess no selective action on malignant tissue.—I am, etc.,

Manchester and District Radium Institute, Sept. 22nd. SYLVIA B. WIGODER, Assistant Radiologist.

PERSONNEL OF A RADIUM CLINIC

SIR,—It would be churlish on my part not to acknowledge the extreme courtesy of *Mr. Duncan Fitzwilliams's* reply to my letter. That he deliberately omitted to include the radiologist from his team would hardly have crossed my mind, knowing as I do that there are quite a number of people in London and in the provinces whose expert knowledge of dosage and of the biology of radium is invaluable. That the radiologist was to be excluded from taking his proper place in the future administration of radium was all too evident until Scotland showed us the way. I will not dwell upon this other than to remark that there was some just reason for my previous comments.—I am, etc.,

London, W.1, Sept. 25th. STANLEY MELVILLE.

TECHNIQUE OF INJECTING VARICOSE VEINS

SIR,—Dr. Charles McCash, in his letter on this subject (*Journal*, September 20th, p. 493), states that in using sodium morrhuate "its oily nature renders thorough cleansing of the syringe between injections more difficult." In my experience it is extremely easy to clean a syringe after using this solution as its very nature tends to act as a cleansing agent in removing all traces of blood, etc., from its interior. The reason is that sodium morrhuate is chemically a soap being the sodium salt of an unsaturated fatty acid. As used in solution form for injecting veins it is an aqueous solution of sodium morrhuate that is generally utilized, not an oily solution. The sodium morrhuate is also generally a "neutral soap" and contains no uncombined free fatty acid and no uncombined oil.

The soapy nature of the solution can be proved easily by the fact that if one puts a little of it in the hand and adds water one can wash the hands with the resultant lather. In my letter to the *Journal* of August 23rd (p. 303), I referred to the "oily" nature of sodium morrhuate acting as a lubricant, whereas the term "soapy" would have been more correct, chemically speaking.

Dr McCash states that he uses short or bevel pointed needles and finds them of great use Personally I gave up using them some time ago, as I found that, owing to their more blunt nature, they tended to push some veins aside rather than enter them directly, unless the vein was firmly fixed—I am, etc,

Leicester Sept 27th F A E SILCOCK M D, D P H

PYREXIA OF UNCERTAIN ORIGIN

SIR,—Regarding Dr W H Palmer's letter in your issue of September 27th (p 543), I had a case a fortnight ago which was very similar to his series The patient was a boy, aged 10, and presented all the signs and symptoms mentioned by Dr Palmer In addition, he had oedema of the upper eyelids and some phlyctennules on his conjunctivae There was a trace of albumin in the urine, and a blood count showed a deficiency of polymorphs, being otherwise normal Recovery was uneventful—I am, etc,

Llansamlet, Swansea Sept 29th T J EVANS

SIR,—The symptoms described by Dr Palmer in your current issue would suggest that these cases may be mild septicaemic cerebro-spinal meningitis, such as I have recently seen here and am publishing records of Most of these cases are exceptionally difficult to confirm unless a relapse occurs, or meningitic signs set in, or a definite case is recognized in the vicinity—I am, etc,

Borough Sanatorium Sunderland, Sept. 30th EUSTACE THORP, M B, L R C S, D P H

NECROPSIES BY GENERAL PRACTITIONERS

SIR,—I am interested in this subject, having been a practitioner covering extensively the whole field of medicine, midwifery, and gynaecology, as well as surgery in all its specialties This, I presume, would entitle me to the term "a general practitioner" To this, among other things, was added the performance of roughly from 100 to 150 medico-legal post-mortem examinations yearly, and the giving of evidence in court on these cases When I commenced I was no better nor worse qualified for the job than the average general practitioner As it was a very important part of my work I had to undertake an intensive study of the subject, so that, on the one hand, I might be an efficient witness in the interests of justice, and that, on the other hand, I should not look a fool when confronted with judicial advocates who knew the subject well In my first few cases I did not feel comfortable in the witness box, and I learnt there what courts required—a thing not taught in any undergraduate school I would have been much more comfortable if I had had a special post-graduate course of instruction in necropsies *and* evidence I do not wonder that general practitioners do not like this work when so very little of it comes their way Reading the reports of such cases, it seems to me that it would be in the interests of justice (as matters stand) that some one or two of the medical members attached to the county councils should do this work, having previously attended a special course of instruction in the subject one of the teachers being an experienced judicial advocate—I am, etc,

Sidcup Sept 23rd HENRY SMITH, C I E, Lieut Colonel I M S (ret.)

SIR,—May I deal with the more relevant protests which my letters on this subject have evoked?

The first and most telling objection is that valuable professional experience would be lost to the general practitioner if he ceased to perform post-mortem examinations The answer to that is that he would gain rather than lose in pathological knowledge by watching them performed by others more skilled than himself We do not complain of losing valuable surgical experience because we send our operation cases to hospital And almost certainly the co-operation of the general practitioner would be required, for surely no necropsy can be complete unless the pathological findings are correlated with the symptoms exhibited during life

The second and less valid objection is a general protest against the invasion of the practitioner's domain by anything that savours of specialism This is where the acid test of efficiency is applied, and no argument of the possessive or sentimental order can stand against it Would the work be done better by a change in organization? If it would, then the change is bound to come, and we should be doing a public disservice by opposing it

The third objection, if indeed I read Dr Gibson correctly (September 20th, p 499), is that we have, or ought to have, sufficient pathological knowledge to perform necropsies efficiently ourselves I agree with Dr Gibson that we leave hospital with perhaps as much pathological as medical or surgical experience, but there the resemblance ends The practice of medicine and surgery is our daily round, we make mistakes, and strive not to make the same mistake twice When we encounter a puzzling case we can ponder it at our leisure, discuss it with colleagues, or consult works of reference But with an isolated post-mortem examination I contend that we have no such opportunity, nor can we have, however keen and interested we may be At a single examination we must come to a definite conclusion from unfamiliar material We must make a pronouncement on oath, and perhaps withstand a searching cross-examination Does Dr Gibson seriously believe that one necropsy a year (a fair average for a country doctor) is sufficient to maintain a satisfactory knowledge of pathological anatomy and post-mortem appearances? Surely not Although, unlike most of us, he appears perfectly satisfied with his own ability in post-mortem examinations, he will no doubt agree that if he had twenty times as many to perform he would become even more skilful That is the whole of my argument Where twenty men will do one examination each and do it badly, one man will do the whole twenty and do them much better

I certainly do not envisage the total exclusion of the ordinary doctor from all post-mortem experience My conception is that some practitioners would undertake these examinations just as some do a certain amount of ophthalmic work, or any other specialty, and by some such system of centralization all the doctors of a district would have the same freedom of access to their local mortuary as they now have to the operating theatre of their local hospital They would thus have a far better opportunity of learning pathology than they have with their present annual necropsy

That there is any objection to the removal of bodies to a mortuary is contrary to existing experience This is the usual course in many large cities, and gives no offence that I have heard of If the body is in a rural district twenty miles from a mortuary, it merely means an extra two hours' absence on the journey—I am, etc,

September 22nd. RUSTICUS

DESICCATED HOG'S STOMACH IN PERNICIOUS ANAEMIA

SIR,—The following case is, I think, worth recording The patient is a man, 67 years of age, who was put on liver treatment on receipt of the following report of the blood

October 11th, 1929—Haemoglobin 38 per cent, colour index 1 2, red corpuscles 1 576 000 per c mm, white corpuscles 3 200 per c mm, polymorphs 59 per cent, lymphocytes 34 per cent, large mononuclears 4 per cent, eosinophils 3 per cent Nucleated reds present (megaloblasts 5 per cent normoblasts 2 per cent) Poly chromasia present Marked variation in size and shape of red cells

January 6th, 1930—Haemoglobin 72 per cent colour index 1 3, red corpuscles 2 832,000 per c mm, white corpuscles 3 200 per c mm

March 3rd, 1930—Haemoglobin 84 per cent, colour index 1 4, red corpuscles 2,984,000 per c mm, white corpuscles 4 200 per c mm

The patient had now been four months under treatment, and, as things seemed rather at a standstill, he was put on ventriculin, as suggested by Dr Renshaw in your issue of February 22nd, beginning with 10 grams and gradually increasing the quantity given, until in a week he was taking 30 grams daily

April 28th, 1930—Haemoglobin 92 per cent colour index just above 1 red corpuscles 4,316,000 per c mm, white corpuscles 4 400 per c mm

June 6th ... 9)—Haemoglobin 86 per cent ... colour index 1 ... red corpuscles 4,981,000 per c.mm ... white corpuscles 5,800 per c.mm.

After this report the amount of ventriculin was reduced to 20 grams a day.

On July 18th 1930 the laboratory report was:

Haemoglobin 82 per cent ... colour index 1 ... red corpuscles 5,010,000 per c.mm ... white corpuscles 6,400 ... Differential count: Polymorphs 70 per cent ... lymphocytes 20 per cent ... large mononuclears 7 per cent ... eosinophils 1 per cent. Practically no variation in size or shape of red cells. No nucleated red cells seen.

He was then advised to reduce his ventriculin to 10 grams a day. He seems quite well and has resumed his usual occupation. There is no doubt that the change from liver treatment to ventriculin was a great factor in hastening his recovery.—I am, etc.,

Exeter, Sept. 22nd. C. F. STORRS.

HARVEY'S DE MOTU

SIR,—In the issue of the *British Medical Journal* for September 20th there is an article (p. 491) entitled "Dr. William Harvey" which deals with the catalogue of Old Medical, Botanical, Chemical, and Alchemical Books" lately issued by the International Antiquarian at Amsterdam. In the article we are asked "Why did he [Harvey] send the manuscript of the *De Motu* to be printed at Leipzig?" But Harvey sent it to Frankfort (on the Main) for we read on the title-page of the first edition—Francofurti, Sumptibus Guilielmi Fitzeri, Anno M.DC.XXVIII."—I am, etc.,

London, Sept. 27th. D. FRASER HARRIS.

*** The learned Harveian who contributed the article writes: When the Rev. Dr. Burgon asked advice of Dr. Routh the old, old, very old President of Magdalen College, Oxford, as to the best course for him to pursue in literature, the venerable President—no doubt with a twinkle in his eye, for Burgon's slapdash method were well known in the University—replied, "Sir, verify your references." Dr. Fraser-Harris does well to point out that I omitted to do so, but the mistake is so glaring that it is clearly a mere slip of the pen. No Harveian would attribute the Fitzers to Leipzig, but the question still awaits an answer.

Obituary

PHOEBE MILDRED BIGLAND, M.D., M.R.C.P.,

Consulting Physician, Liverpool Dispensary for Women.

THE all too early death of Dr. Phoebe Bigland on September 24th, at Rodney Street, Liverpool, removes from medical circles in that city one whose place will be hard to fill.

Obtaining the M.D. degree of the University of Liverpool at a comparatively early age, she became M.R.C.P. Lond. in 1919, and her record includes appointments in both cities. She had been house-surgeon at the Royal Free Hospital, London, and she held a similar appointment in the Stanley Hospital, Liverpool, where during the war she became acting physician. She was successively medical tutor and registrar and temporary honorary assistant physician at Liverpool Royal Infirmary and honorary assistant physician at the Liverpool Chest Hospital. On the academic side she held successively the appointments of John W. Garrett Fellow in Pathology, demonstrator in pathology, and assistant lecturer in the same subject. Turning to another field she became assistant school medical officer. The appointments she held at the time of her death reflect her special interest in the diseases of women and children, including as they did honorary physician, Crofton Convalescent Hospital, honorary consulting physician, Liverpool Dispensary for Women and Children, medical officer Infant Welfare Clinics, assistant Venereal Diseases Department Royal Infirmary, and medical officer in charge Mothers' Welfare Clinic.

Her contributions to medical literature began in association with the late Dr. O. T. Williams in 1912. The subject in which she specially interested herself in later years is shown by her contribution in 1922 to the ninth annual report of the Board of Control (with Watson and Bigland) on the influence of syphilis in mental cases, followed by an article in the *Lancet* in 1923 with the same collaborators on the relation between general paralysis and somatic syphilis, the effect of treatment on the Wassermann reaction of syphilitic patients, contributed to the Medical Research Council Report of 1926 (with Dr. Glenn), and studies connected with the same subject which appeared in the *British Journal for Venereal Diseases* in April 1927. Her sympathy with students and her insight into their special difficulties will be gratefully remembered by numbers of ex-students of Liverpool University. Her fellow practitioners marked their appreciation of her loyalty to the interests of medical women and her strenuous work on their behalf by making her president of the Liverpool Association of the Federation of Medical Women, and her ready wit and quick grasp of essentials will be remembered by the council of the Federation of Medical Women, of which she was for many years a member.

She married Dr. Douglas Bigland in 1917 and her charming hospitality and the happiness of her home life will be a grateful memory to a very wide circle of friends. Those among whom he worked will appreciate her loss most acutely. For the husband and two children whom she leaves behind her premature death is a tragedy.

DR. ARTHUR HOLT of Chingford died on September 16th at St. Leonards-on-Sea, at the age of 67. His medical education was obtained in the University of Glasgow, where he graduated M.B., C.M. in 1895. He then practised for some time in Horwood, where he took a special interest in puerperal septicaemia and strongly supported a movement among medical practitioners for the instruction of midwives in the use of antiseptics. He was also largely concerned in introducing bimanual compression for postpartum haemorrhage. Failure in health then necessitated his taking a sea voyage after which he undertook general practice in London. During the war Dr. Holt's house in Lewisham was struck by a bomb; the whole family escaped but the shock to him was so severe that he never fully recovered. He retired from practice four years ago but subsequently resumed at Chingford. A colleague writes: Dr. Holt endeared himself to his patients by his conscientiousness and by the deep interest he took in the nature of their illnesses. As a friend he was sincere and faithful. In company he was genial and full of humour; no one could tell a story better, and no one could do it the same way. He was buried at Cheshunt on September 22nd where his wife had been laid two years earlier. He leaves one daughter and two sons.

MR. WALTER EDMUNDS of Putney, who died at Worthing on September 23rd at the age of 80, received his medical education at Cambridge and St. Thomas's Hospital. He graduated M.B. Camb. in 1875, and proceeded M.Ch. in 1877; in this year also he received the diploma F.R.C.S. Eng. by examination. He took part in the Turko-Russian war of 1877–78 as surgeon, and was later appointed surgeon to the Prince of Wales's General Hospital, Tottenham, being subsequently elected consulting surgeon. He had been a member of the British Medical Association and of the Ophthalmological Society. In 1901 he delivered the Erasmus Wilson Lecture to the Royal College of Surgeons. He took a special interest in diseases of the thyroid gland and published many contributions on this subject.

The following well-known foreign medical men have recently died: Professor DEODATO DE CARLI, professor of oto-rhino-laryngology at Naples, aged 55. Professor HJALMAR FORSSNER, a Swedish gynaecologist, aged 57. Dr. KARL BAYER, professor of surgery at the German University at Prague, aged 76. Dr. V. JANSKO, professor of internal medicine at Szeged, aged 61. Dr. PAUL PEYER, extraordinary professor of pathology and morbid anatomy at Bonn, aged 48. And Professor JOHANN FABRY, a dermatologist of Dortmund, aged 69.

The Services

DEATHS IN THE SERVICES

Surgeon Captain Douglas Duke Turner, R N (ret), died in the Royal Naval Hospital Haslar on August 4th, aged 53. He was educated at St Thomas's, took the M R C S and L R C P Lond in 1900, and after filling the posts of house surgeon and house physician of the Victoria Hospital for Children, Chelsea, and of assistant medical officer of Paddington Infirmary, entered the navy as surgeon on May 23rd, 1904. He was promoted to staff surgeon after eight years' service and to surgeon commander in June 1917, and retired with an honorary step of rank as surgeon captain in March, 1927. During the war he served as medical officer of the cruisers *Sappho* and *Devonshire*, and after the war in the cruiser *Concord*, in the battleship *Resolution*, and in H M S *Defiance*, torpedo school ship at Devonport.

Colonel George James Hamilton Bell, C I E, Bengal Medical Service (ret.), died in Edinburgh on July 9th, aged 61. He was born on February 28th, 1861, the son of Robert Bell, Sheriff Substitute of Stirling, Dumbarton, and Clackmannan, and was educated at Edinburgh Academy and at the University in that city, where he graduated as M B and C M in 1882. Entering the I M S as surgeon on April 1st 1886, he became colonel on June 16th, 1915, and retired on August 20th, 1920. He served in the Burmese war in 1887–89, receiving the Frontier medal with a clasp, and in the Lushai expedition on the Eastern Frontier in 1889 (clasp). He then got civil employment in Bengal, but before long was transferred to Burma for service in the Jail Department there, of which he became inspector-general. In June, 1915, he was appointed Inspector General of Civil Hospitals in Burma, but towards the close of that year was transferred to the same post in Bihar and Orissa on the death of Colonel F J Dimn. He received the C I E on June 2nd, 1914. In 1890 he married Violet Helen Mary, daughter of Lestock Reid Forbes, Esq., and had a son and two daughters.

Captain Edward Chandler, R A M C (ret.) died at Aberstoke on June 14th, aged 88. He was born at Alston Cumberland, on October 14th 1841, was educated at Charing Cross Hospital, and took the L R C P Lond in 1862 and the M R C S in 1863. He entered the A M D as surgeon on April 14th 1863, became surgeon major on April 1st, 1873, and retired on half pay on February 4th, 1875, his designation being changed to surgeon captain in 1893 and captain in 1898. In the old regimental days he served in the Royal Artillery and after retirement was employed for some years as medical officer of the military prison at Gosport. He served in the New Zealand war of 1864–66 receiving the medal. He must have been one of the oldest retired medical officers, if not actually the oldest.

Universities and Colleges

UNIVERSITY OF LONDON

The Geoffrey F Duveen Travelling Studentship in Oto-rhino-laryngology of the value of £450 will be awarded annually. The tenure of the studentship shall be, in the first instance, for one year, part of which will be spent in study abroad, in accordance with a scheme to be approved by the Board. The tenure may be extended for one or two years and during such extended period the student may be allowed to undertake research at the Royal Ear Hospital or some other laboratory approved for the purpose. Grants for promotion of research in oto-rhino-laryngology or in any part thereof may also be made from the trust fund of the benefaction. No person shall be qualified for election to the studentship or to receive grants from the fund until he or she has obtained the degree of M B and B S in the University. Applications should be made on the prescribed form obtainable from the Academic Registrar of the University, London S W 7, to whom they should be sent by December 21st 1930 together with a statement of the nature of the research proposed and a scheme of study.

A Paul Reitlinger Prize of £30 for the best essay embodying the result of some research work on a medical subject carried out by the candidate will be awarded on December 3rd 1930 provided there be a candidate of sufficient merit. Candidates must be matriculated students who on June 1st preceding the award, were studying in one of the schools of the University in the Faculty of Medicine or graduates of the University who on the same date, were of not more than five years standing from the date of taking their first degree and who are or were students in such school. Regulations of the award of the prize may be obtained on application to the Academic Registrar.

The next award of the Rogers Prize of £100 will be made in 1931. The subject selected is Filterable viruses as a cause of disease in man. The prize is open for competition to all persons whose names appear on the *Medical Register* of the United Kingdom. Copies of the regulations including information regarding the date in April by which entries must be received and any further information, may be obtained on application to the Academic Registrar.

KING'S COLLEGE

Four lectures on metabolism of the carbohydrates and fats will be given by Dr J A Hewitt on Thursdays October 16th, 23rd, 30th, and November 6th, at 5 p m. Admission is free without ticket.

UNIVERSITY COLLEGE

The session 1930-31 opens at University College on Monday, October 6th. First year students of the Faculty of Medical Sciences will be received between 10 a m and 1 p m, those of later years between 2 15 p m and 4 p m.

Mr J C R Hindemarch, M B, Ch B, and Mr C P Bryan, M B, B Ch, have been appointed demonstrators in the department of anatomy and embryology.

Among the public lectures arranged for the first term are the following: 'Introduction to the theory and practice of experimental embryology' (two lectures), by Professor H Spemann of the University of Freiburg; "The reticulo-endothelial system" (four lectures), by Dr H P Gilding; The respiratory functions of the blood (four lectures), by Dr L L Bayliss. The complete programme, giving particulars of these and other lectures open to the public without fee or ticket, may be had on application to the secretary of the College. A stamped addressed envelope should be enclosed.

WESTMINSTER HOSPITAL MEDICAL SCHOOL

The following prizes have been awarded:

Chadwick Prize for Clinical Surgery J G Stewart and Miss F T Davies equal; Class Prize in Surgery D H H Thomas; Chadwick Prize G J Griffiths; Abrahams Prize W P Jonson; Sturges Prize I S Lee; Frederick Bird Medal and Prize G J Griffiths; Hanbury Prize F S Lee; Class Prize in Midwifery D G Cowor; Class Prize in Medicine Miss I Curphey; Class Prize in Forensic Medicine and Toxicology W Dran; Class Prize in Public Health Miss I Curphey; Class Prize in Bacteriology (Dr Hicks's Prize) Miss G I Matthews.

UNIVERSITY OF LEEDS

The following candidates have been approved at the examinations indicated:

M D—I Berenblum Elsie G M Ford Bessie Goodson D Perk
Ch M—D W Currie
FINAL M B, Ch B—*Part I* B W A Fleming L Glick F C Leach N W Roberts K I Tunbridge Lillian I Walker; *Part II and Part III (New Regulations)* G M Holliday I J Keidan *J Shernovitch S Silman; *Part II (Old Regulations)* M Goodman J N Hill G Hirst G J Marks B S Platt
D P M—I J Graham G C Morris
D P H—Rosie B Becker I J S Bonnett A R Doyle J L M Wood, Hester E de C Woodcock

* Awarded second class honours.

The West Riding Panel Practitioners Prize for proficiency in medicine was awarded to J Shernovitch.

Medical News.

The annual reunion dinner of the London (Royal Free Hospital) School of Medicine for Women will be held at the Savoy Hotel on Thursday, December 4th, at 7 for 7 30 p m. The honorary secretary of the dinner committee is Miss Sibyl F Widdows.

The annual dinner of the staff and past and present students of the Royal Dental Hospital of London will be held at 7 p m on Saturday, November 22nd, at the Trocadero, with Dr Harvey Hilliard, C B E, in the chair. The Medical Committee will be "at home" to all past and present students of the hospital on the same day from 9 30 a m to 5 p m. In the morning demonstrations will be given by members of the staff and lecturers. In the afternoon orthodontic and other cases of special interest from the clinic of the hospital will be shown, the various departments of the hospital and school will be open for inspection. All medical practitioners are cordially invited.

The twenty-sixth annual dinner of the Birmingham and District Edinburgh University Club will be held at the Queen's Hotel, Birmingham, on Thursday October 23rd at 7 p m. The chair will be taken by Professor J C Brash, and Professor John Fraser of Edinburgh has consented to be the guest of the club. Membership of the club is open to all male graduates of the university, and any who would like to attend the dinner and have not received details of it are requested to write to the honorary secretary, Dr Ernest Bulmer, 87, Cornwall Street, Birmingham.

The Annual Dinner of the Chelsea Clinical Society will be held on Tuesday, October 28th, at 7 30 p m, at the Rembrandt Hotel.

The opening meeting of the Torquay and District Medical Society for the session 1930–31 will be held at the Torbay Hospital on October 16th when a paper will be read by Dr W Langdon Brown on the present position of endocrinology.

A meeting of the Biochemical Society will be held in the Biochemical Laboratory, Cambridge, to-day (Saturday, October 4th), at 3 p m, when papers will be read and demonstrations given.

AT the opening meeting of the St Pancras Division to be held in the British Medical Association's House Tavistock Square on Tuesday October 14th at 9 p m, Sir Harold Gillies will give a lantern demonstration of methods and results in plastic surgery

THE Crenfell Association of Great Britain and Ireland has arranged a meeting to be held at the Mansion House on Thursday October 16th at 3 p m under the chairmanship of the Lord Mayor of London Sir Wilfred Crenfell K C M G M D will give an account of his work in Labrador, and Field Marshal Viscount Allenby will also address the meeting

A MEETING of the Illuminating Engineering Society will be held at 15 Savoy Street Strand W C 1, at 6 30 p m on Wednesday October 8th when a report on progress in illuminating engineering prepared by the Technical Committee, will be presented and exhibits illustrating recent developments will be displayed

THE French Society of Orthopaedics will hold its annual meeting in Paris on October 10th when the following subjects will be discussed coxa vara of adolescents introduced by Dr Huc of Paris and obstetrical paralysis of the upper limb, introduced by Dr Andre Rendu of Lyons

THE Fellowship of Medicine announces that there is still one week of the intensive course in medicine surgery and the special departments at the Metropolitan Hospital From October 6th to 25th there will be a special course in ear nose and throat diseases at the Central London Throat Nose and Ear Hospital consisting of a clinical course an operative class (limited) and a pathology class At the Chelsea Hospital a course in gynaecology will continue from October 13th to 24th The Fellowship of Medicine has arranged an evening course of seventeen lectures suitable for (though not confined to) candidates for the M R C P examination The first lecture will be delivered on Tuesday, October 7th by Dr L J Witts, who will describe recent work on the liver the second lecture also given by Dr Witts on October 10th will deal with blood diseases The lectures will be given at the Medical Society, 11, Chandos Street, Cavendish Square, W 1 at 8 30 p m At the same place a course of evening demonstrations for the F R C S (final) will be given one day a week for six weeks at 8 30 p m beginning on October 8th, and consisting of demonstrations in clinical surgery and pathology Four demonstrators will attend each evening and will provide two cases each The fee for the course is £5 5s and contrary to the statement made on the syllabus itself, it must be paid in advance tickets cannot be issued at the lecture hall Particulars and syllabuses of all courses may be obtained from the secretary of the Fellowship 1, Wimpole Street W 1

A POST GRADUATE course has been arranged at the Royal National Orthopaedic Hospital under the auspices of the Fellowship of Medicine and will be held from October 27th to November 8th Daily lecture demonstrations will be given by the staff at 11 30 a m, except on the two Saturdays when visits will be paid to the Brockley Hill Country Hospital Those taking part in the course are specially invited to attend the operative and out patient practice of the hospital each day The fee for the course is 3 guineas and applications should be sent to the secretary of the hospital 234 Great Portland Street, W 1 or to the secretary of the Fellowship of Medicine, 1 Wimpole Street W 1, in either case by October 20th The minimum entry is ten

A COURSE on diseases of the heart and vessels will be held at the Hôpital Broussais Paris under the direction of Dr Laubry from October 13th to 25th The fee is 150 francs, which should be sent to Dr Mevel Hopital Broussais, Rue Didot 96, Paris XIV

A COURSE of ten lectures on the prevention of accidents, disorders and disease will be delivered in the lecture hall of the Royal Institute of Public Health Russell Square W C 1 on Wednesday afternoons at 4 o clock from October 15th to December 17th In the first lecture Dr E Graham Little will discuss the prevention of accidents disorders and disease in members of the medical and nursing professions Professor Lazarus Barlow will deal with the prevention of precancerous states and the arrest of cancer in the second lecture, Lieutenant Colonel J A A Pickard will give the third lecture on the prevention of street accidents and will illustrate the subjects with lantern slides The remaining lectures in the series will relate to the preventive aspects of tuberculosis, venereal disease accidents in workshops tropical disorders mental illness and industrial diseases The lectures are free to medical practitioners The Harben Lectures will be delivered at the Institute on October 6th 7th and 8th, at 4 p m, by Professor W H Park director of the Bureau of Laboratories New York City his subject will be pneumonia The annual congress of the Institute in 1931 will be held in Frankfort during Whitsuntide Further particulars may be obtained from the honorary secretary of the Institute 37, Russell Square W C 1

A COURSE of twenty four lectures for general practitioners on psychological types and mechanisms opened on October 1st at the Tavistock Square Clinic for Functional Nervous Diseases 51 Tavistock Square W C 1 The remaining lectures of the course will be given by Dr Crich on Miller and Dr Graham Howe on Wednesdays at 3 and 4 30 p m from October 8th to December 17th inclusive The fee for either series is £1 11s 6d and for both £2 2s

THE seventeeth annual French Congress of Hygiene will be held at the Institut Pasteur Paris from October 20th to 23rd under the presidency of Professor Delépine member of the Académie de Medecine The following subjects will be discussed successive changes in French pharmacopoeias introduced by Professor Delepine, comparative statistics of infantile mortality introduced by Dr Lesage study of the reports of health offices, by MM Aublant and Prunet and M.I Brocquin Lacombe and Bonnet and hygiene and reconstruction in the inundated districts in the South of France Lectures will be given on psittacosis by Professor Sacquepée and on Lavoisier as hygienist by Dr Dujarric de la Rivière Further information about the congress can be obtained from Dr Dufaure, Institut Pasteur, 28 Rue Dutot, Paris XV

THE thirty seventh Congress of the Italian Society of Surgery will be held in Rome from October 13th to 16th, when the following subjects will be discussed treatment of cranio cerebral trauma apart from gunshot wounds introduced by Egidi and Giacobbe of Rome and Alberti of Brescia and the diagnosis and treatment of haematuria, introduced by Lasio of Milan and Ferrata of Padua

MR K J ACTON DAVIS consulting orthopaedic surgeon to the London County Council, gave a lecture on the treatment of the modern cripple child at a meeting of the cripple superintendents and helpers of the Shaftesbury Society which was held at the Central Hall, Westminster, on September 24th He warmly commended the action of this society in establishing residential homes and schools for cripple children between the ages of 2 and 16 and as a result of his own experience was satisfied that such treatment enabled patients to return benefited to their homes and then to continue to improve The voluntary workers of the society had proved particularly useful in ensuring the co-operation of the parents, and instructing them how the best results could be obtained Emphasis was laid by the superintendent of the society's cripple department on the importance of discovering early cases of crippling defect so that children could receive surgical attention before the disability had progressed too far

THE Save the Children International Union, Geneva, has decided to form a section for preventive paediatrics This will be composed entirely of physicians and will deal with the scientific study of the prophylaxis of children's diseases and related questions of organization and instruction Its headquarters will serve as an information and liaison centre for physicians and others who are interested in child hygiene and who may wish to make interstaff exchanges or undertake studies in other countries The lines upon which this new section is to be conducted have been fixed by a number of well known paediatrists, including Professors Lereboullet (Paris) Parsons (Birmingham), Valagussa (Rome) Schlossmann (Düsseldorf), Hamburger (Vienna), and G Scheltema (Groningen Holland) Professor Scheltema has undertaken the work of organizing the section and is temporarily in charge of its secretariat further information may be obtained from him

DR. F FELIX JONES on his retirement after fifty years of practice at Llanfyllin Montgomeryshire has been presented by the inhabitants of the borough of Llanfyllin with a silver tray suitably inscribed by the Llanfyllin Board of Guardians with a framed illuminated address and album of subscribers names by the indoor staff of the Llanfyllin Poor Law Institution with a silver cigarette case and by the inmates with a silver flask.

DR. J R LORD C B E F R C P Ed medical superintendent of Horton Mental Hospital Epsom and lecturer in clinical psychiatry London (Royal Free Hospital) School of Medicine for Women has been appointed by the Minister of Health a member of the General Nursing Council for England and Wales

WE have received the first issue dated Sep ember 1930 of *Kinderärztliche Praxis* a quarterly journal edited by Professor St Engel of Dortmund and Dr F Nassau of Berlin and published by Georg Thieme of Leipzig, at the price of 7 marks Its aim is to provide the general practitioner, paediatrist and hygienist with information as to recent progress in all branches of paediatrics

THE Minister of Health the R Hon Arthur Greenwood, M P has appointed Miss E M R Russell Smith to be his assistant private secretary and the Parliamentary Secretary to the Ministry Miss Susan Lawrence M.P has appointed Mr S F S Hearder to be her private secretary

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR British Medical Journal, British Medical Association House, Tavistock Square, W C 1***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House Tavistock Square, W C 1, on receipt of proofs

All communications with reference to ADVERTISEMENTS as well as orders for copies of the *Journal* should be addressed to the Financial Secretary and Business Manager

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863* and *9864* (internal exchange four lines)

The ***TELEGRAPHIC ADDRESSES*** are

EDITOR OF THE *BRITISH MEDICAL JOURNAL, Aitiology Westcent London*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc), *Articulate Westcent London*

MEDICAL SECRETARY *Mediocrity Westcent London*

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams *Bacillus, Dublin*, telephone 62550 Dublin), and of the Scottish Office 7, Drumsheugh Gardens, Edinburgh (telegrams *Associate, Edinburgh*, telephone 24361 Edinburgh)

QUERIES AND ANSWERS

? CHEIROPOMPHOLYX

"SYMINGTON" asks if any of his professional brethren can assist him in tracing the cause of a dermatitis that occurs in his hand now and then It starts with a benumbed feeling about and between his fingers followed by intolerable itching, papules, and small vesicles which become pustules, then lymphangitis and enlarged glands in the axilla and seems to defy all remedies It has been called gout, rheumatism, neuritis, etc, by specialists He understands it has affected other medical men

PYLORIC CANCER REMISSION OF SYMPTOMS

MR A P BERTWISTLE (London, W 1) writes In reply to 'Wicklow's inquiry in the *Journal* of September 13th (p 455), two possibilities occur to me as regards the case recorded, only an operation could clinch the diagnosis In the first place the case may be one of benign gastric neoplasm, the Mayo Clinic states that as many as 2 per cent of gastric tumours are benign A polypus in the pyloric canal would cause spasmodic pain in the stomach, gaseous eructations, loss of weight by starving, possibly haematemesis and melaena, and a 'filling defect' on radiographic examination identical with that of cancer In the second place, is the case one of gastric syphilis? Since these cases do not often come to necropsy, little is known of them, though there is considerable literature on them in France, and Carman mentions them in his work on radiology

ANHYDROSIS AND ABSCESS

DR R H THOMSON (Uphall, West Lothian) writes In reply to Dr Johnston McNab's inquiry on September 13th (p 456), I have had three cases similar to those reported by Dr A Kendrew on September 20th (p 504), as the result of using a well known and much advertised proprietary depilatory One patient was especially ill, being confined to bed for fully three weeks High temperature and rapid pulse continued, even after the abscesses had been incised and drained I feared that a general septicaemia might ensue, however, the patient made a slow but good recovery

INCOME TAX

Valuation of Property

"G L B points out that the forms now being issued require taxpayers to state whether their houses are occupied solely as private residences or partly for business or professional purposes, Will that fact affect the valuation to be made for income tax, Schedule A?

*** No doubt the authorities desire to have as full particulars of the premises as possible, but the basis of valuation is the letting value in open market, and the purpose for which the premises are used seems immaterial, unless it indicates some special site value

Payment of Capital by Instalments

T S has purchased a share in a partnership on terms which allow him to discharge the capital sum by instalments consisting partly of principal and partly of interest on the principal outstanding Can he deduct the amounts of interest for income tax purposes?

The interest should be specifically shown as deductions in the statement of total income from all sources in the space provided for "charges on income" But 'T S" will have to pay tax at the standard rate on that interest On the other hand, when he pays the interest, he should deduct tax from it at the standard rate, so that in the end the tax will have been suffered by the recipient of the interest and not by himself—as, of course, is the proper result

LETTERS NOTES ETC

PASTEURIZATION AND MILK BORNE EPIDEMICS

MR P B TUSTIN, technical adviser to United Dairies Ltd, and formerly chief of Food and Dairy Division, City of Winnipeg, writes I note in your issue of August 16th (p 255) an article on the pasteurization of milk in Canada, referring to the annual report of Dr A J Douglas medical officer of health for Winnipeg You say "Experts in Great Britain will prefer to think that where adequate precautions have been taken pasteurization is needless There have been three recent milk borne epidemics in Great Britain The paratyphoid outbreak in Kensington was due to raw cream, the outbreak of sickness among Leeds school children was traced to raw milk, and the outbreak of septic sore throat at Brighton was due to raw milk Dr D Forbes, the medical officer of health for Brighton points out in his annual report for 1929 that in his view pasteurized milk is the only designated milk which gives protection to consumers I know of no milk borne epidemic in this country that has been traced to properly pasteurized milk or cream The figures in the official report of the United States Health Service for 1926-27-28 on milk borne epidemics, including outbreaks of typhoid, paratyphoid septic sore throat, scarlet fever diphtheria, gastro-enteritis and Malta fever, are as follows —1926 68 epidemics, 3 363 cases, 95 deaths, all reported as caused by raw milk, 1 of septic sore throat at Hamden, Conn, due to certified milk 1927 36 epidemics 952 cases, 41 deaths 1928 43 epidemics, 2,129 cases, 94 deaths, all reported as caused by raw milk, none to pasteurized milk

PREGNANCY AND CERTIFICATION

DR D C MURRAY PAGE (Pittenweem, Fifeshire) writes In connexion with the note from "H R" on Pregnancy and Certification (*Journal*, September 20th, p 504) may I relate my sole experience regarding this matter In July a married panel patient asked to be signed on the panel, since she was seven months pregnant and her insurance agent told her that she was entitled to benefit She was quite fit, and working away in the house and baiting fish lines every day I told her that I did not think she was entitled to benefit, but that I would write to the Scottish Board of Health for advice In his reply the Secretary to the Department of Health for Scotland said that no woman was entitled, on the occasion of her confinement, to receive sickness or disablement benefit as a matter of right prior to confinement These benefits could only be paid if there was incapacity for work, and that condition must be satisfied in every case The society's agent had misinformed the insured person, and I understand that he was properly dealt with by his superiors

UNOFFICIAL AUNTS

MRS E W HARDY (7, Dailey Avenue, W Didsbury, Manchester) writes The Voluntary Unofficial Aunts will be pleased to help in the following and similar ways (1) To stay in the house in charge of children to enable the parents to go out together for an hour or two (2) To take children out, or to the doctor dentist, hospital, etc (3) To visit old or feeble people read to them or play a game with them, and so occasionally to give relief to the one in charge (4) To sew or mend garments sent to those "aunts" unable to do outside work The "V U A" are purely voluntary workers, anxious to help but not qualified in any way They accept no responsibility, but will do their best to be of service although of course, they are not prepared to replace ordinary domestic labour or trained nursing Anyone desiring to help, or to be helped, should apply to me

CORRIGENDA

The Mechanism of Swallowing

WE regret that the concluding remarks by Mr John F O'Malley in the discussion on this subject before the Section of Radiology at Winnipeg were erroneously recorded in the *Journal* of September 20th (p 486) The sentence should have read as follows "He had pointed out some four years ago that in the human foetus at five months the epiglottis was in the nasopharynx, which was the position in the adult whale and alligator, and such animals had no difficulty in swallowing without any falling over of the epiglottis"

In our report of the discussion on functional disorders of the colon (September 20th, p 474) Dr Hugh Barber of Derby was incorrectly described as coming from London

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 51, 52 53, 54, 55 56 57 61 and 62 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 58 59, and 60

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 159

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

301 The Psychotoxic Heart

M D SILFERBERG (*New Zealand Med Journ*, April, 1930 p 62) considers that functional disorder of the heart is the cause of symptoms in more than 10 per cent of all patients with complaints referable to the cardiovascular system Although the exposure and infections incidental to war conditions have been responsible for large numbers of cases, this disorder is not uncommon in civilian communities both among the constitutionally weak and the robust Factors responsible for this functional state are faults in education and upbringing and disturbances of endocrine balance Toxic factors play an important part as is evidenced by the easy fatigability of the patients the alimentary disturbance, lack of concentration and the sallow, muddy complexion In view of the usual combination of psychical and toxic elements in this disorder the author claims that the term psychotoxic heart is the best name for it The chief complaints are undue breathlessness palpitation and tachycardia following minor degrees of physical and emotional stress fine tremor and sweating may also be observed Fear reactions are very common and may give rise at first to vague anxiety later this is found to concern certain particular functions as in sexual neurasthenia or certain diseases such as syphilis or cancer Three illustrative cases are described showing the etiological importance of infective states endocrine disturbances and anxiety The prognosis as regards a return to heavy occupations is bad complications are uncommon and the psychotoxic heart is not a cause of death Treatment should first be directed toward the removal of past or present infections early cases are frequently benefited in this way From the psychological aspect an attempt should be made to determine the nature of the underlying anxiety or fear, to adjust social or economic difficulties and to inspire a more philosophical outlook Graduated exercise and physiotherapy are indicated in milder cases

302. Paratyphoid A Fever in Australia.

F L APPERLY and A J BRENNAN (*Med Journ of Australia* April 19th 1930 p 525) state that before the war paratyphoid A fever though fairly common in India was rare elsewhere, but during the war it appeared in Gallipoli and France The authors now record the first case which has been published in Australia The patient was a medical practitioner aged 35, who had never been out of Australia A week before the onset of his illness he had been attending a girl with typical typhoid fever who died of meningitis Attempts to trace her infection were fruitless His disease was first diagnosed as chronic appendicitis and then influenza but the correct diagnosis was established by isolating *J paratyphosus* A from the blood and agglutinating it with *B paratyphosus* A serum in a 1 in 10 400 dilution with *B typhosus* and *B paratyphosus* B serums, each diluted 1 in 40 Recovery was uncomplicated after thirteen weeks illness

303 Coughing as a Manifestation of Hypersensitiveness

A COLMES and F M RACKEMANN (*Journ Amer Med Assoc* July 19th, 1930, p 192) point out that the coughing which often accompanies vasomotor rhinitis and bronchospasm and which is generally regarded as secondary to those conditions may be an independent symptom of allergy In a previously reported case a cough unaccompanied by either vasomotor rhinitis or wheezing was shown to be a manifestation of human hypersensitiveness to orris powder and notes of three typical similar examples are given In these a definite history of allergy led to the discovery of positive skin tests with the relief of symptoms when the corresponding allergens were eliminated It is pointed out that an existing hypersensitiveness often manifests itself only in the course of an acute infection which lowers the threshold so that a slight exposure suffices to cause trouble this is observable for example when contact with a dog during a cold results in asthma The authors believe that such allergic cough without the presence of wheezing or rales is a new possibility which has hitherto been unrecognized They point out that when such hypersensitiveness forms the background in pulmonary or nasal disease the elimination of the offending allergen may result in marked amelioration of the disease, even in its advanced stages

304 Allergic Migraine

SOME writers have noted a similarity between asthma hay fever and migraine and Vaughan reported a series of cases from which it appears that migraine of all ages is often associated with a specific sensitization to one or more food proteins R M BALYEAT and FANNIE L BRITTAIN (*Amer Journ Med Sci* August 1930 p 212) conclude from a study of 55 patients that practically all cases of true migraine have as an exciting factor a sensitization to foreign protein their treatment, based on the allergic findings has given results as good as or better than those obtained in any other chronic disease The ages of the patients 23 of whom were males and 32 females) ranged from 6 to 62 years and a family history of allergy was elicited in 85 4 per cent The hereditary factor in migraine appears to be interchangeable in linkage with asthma and hay fever, which is evidence that these syndromes have a common etiology—namely specific sensitization Predisposing factors are physical and mental fatigue and depressed states thyroid dysfunction genital causes toxic states, and disturbances of the special senses Migraine patients are usually above the average both mentally and physically and the syndrome occurs more commonly in those whose sympathetic system is highly developed and who are very active mentally The onset of symptoms occurred in nearly one third of the cases during the first decade, the persistence of symptoms until and through the sixth decade is not uncommon In diagnosis the scratch method of testing should first be used although doubtful reactions being checked by the intradermal method Multiple sensitivity is the rule all patients except one in the series were found sensitive to more than one protein The authors add that migraine must be differentiated from functional headaches trifacial neuralgia, myalgia ordinary intoxication and infections, and from headaches due to pituitary dysfunction As regards life and death, and also complications the prognosis is good Treatment should consist of thorough elimination of the foods and dusts to which the patient is found specifically sensitive Five illustrative cases are briefly described

305 Nervous Complications of Varicella.

V BOPPA (*Ric di Clin Med*, April 1930 p 273) reviews the literature and records two personal cases The first was that of a boy aged 4 years who developed acute cerebellar ataxia on the fourth day of disease recovery ensued in about a month's time The second case was that of a girl aged 8 years who after an attack of varicella accompanied by high fever of several days duration, developed encephalitis manifested by left external strabismus and dilatation of the left pupil The child also suffered from loss of memory and became emotional Improvement began in a few weeks

Surgery.

298 Spinal Cord Tumours.

J B AYER (*New England Journ of Med* August 14th 1930 p 295) describes the symptoms and signs of tumours involving the spinal cord, as revealed by a retrospective study of 64 cases 61 of which were found at operation and 3 after death The cases fall into four pathological groups intramedullary tumours probably all gliomata meningiomas (neurofibroma and arachnoid fibroma) extradural haemangiomas and sarcoma and chondromas The age and sex of the patients proved to be of no diagnostic value While 5 years was the age of the youngest patient and 72 that of the oldest, the majority were in the prime of life Though the sexes as a whole were equally divided males preponderated in the glioma group and females in the meningiomas The dorsal cord was the tumour site in 35 cases and the cervical in 26 while in 2 cases the growth was diffuse Ayer remarks that an intraspinal tumour may be as large as a robin's egg before signs or symptoms are noted but usually two sets of symptoms arise before this size is attained sensory and motor disturbances develop in parts of the body innervated from below the site of the growth Sensory symptoms are soon observed and early pain is usual So called root pain is undoubtedly caused by direct stimulation of one or more sensory nerve roots and is an early, persistent and localizing symptom in tumours growing from the sheath of a sensory nerve Spinal pain often severe, is of no localizing value Areas of paraesthesia

may indicate nerve root irritation Numbness is frequent below a tumour, and the level at which the numbness ceases and normal sensation begins should be defined Motor symptoms are constant and often early, they usually consist of spasticity of the extremities due to cord compression Spastic paraplegia suggests a dorsal tumour, quadriplegia a cervical one Spasms, cramps, and attacks of trembling are frequent and troublesome Paralysis with atrophy of arm muscles is of great localizing value Constipation is almost universal, and bladder dysfunction is often early Signs of irritation or paralysis of the cervical sympathetic should always be looked for In suspicious cases the spinal fluid should be examined, since there may thus be revealed an interruption of the fluid pathway in the subarachnoid space, and an increase in fluid protein Spinal tumours must be differentiated from other tumours, tuberculosis, and osteomyelitis, and from degenerative diseases of the cord, particularly multiple sclerosis, haematomyelia, and myelitis The duration of symptoms preceding operation was as follows in gliomas, 6 weeks to 6 years, average 26 months, in fibromas, 5 weeks to 7 years, average 24 months, in extradural tumours 7 weeks to 1 year, average 8 months, and in chondromas, 3 months to 7 years, average 30 months

307 Surgical Treatment in Diabetes

A T BAZIN (*Canadian Med Assoc Journ*, August, 1930, p 146) considers that with the discovery of insulin the operative treatment of a properly controlled diabetic patient is associated with no higher mortality than that in the case of a non diabetic To demonstrate this, tables are given of 221 cases of diabetes admitted to the Montreal General Hospital during 1929 The surgical cases numbered 87, and 73 operations were performed, with only 2 deaths (2 74 per cent), during the same period the total post operative mortality was 2 41 per cent Routine blood sugar and urine analyses are imperative, especially the former Certain surgical problems presented by this disease are discussed, the first one dealt with being what is termed the "acute diabetic abdomen" Two cases are recorded to illustrate this point The differential diagnosis between this condition and that of acute abdominal lesions is as follows With an acute abdominal lesion there may or may not be fever, pain, vomiting, and leucocytosis are present, and the pain precedes the vomiting In the diabetic acute abdomen there may be fever, pain, vomiting, and a high leucocytosis are usually present, but the vomiting precedes the pain Moreover, there is an indefinite diffuseness in the abdominal symptoms, and the general disturbance is out of proportion to the abdominal findings Bazin thinks it safer to operate in such cases The second problem considered is the influence of diabetes on healing and the resistance to infection Many patients are discovered whose faulty healing or development of a low grade skin infection depends on a disturbed carbohydrate metabolism Small doses of insulin are useful in such conditions, and an illustrative case is cited Thirdly, diabetic gangrene of the foot is discussed, and two varieties are defined In one group the active etiological factor is infection, treatment comprising both the diabetes and the infection In the second this factor is circulatory (capillary blocking), here insulin is indicated, and Buerger's teachings are important Indications as to the correct site of amputation are given Finally, Bazin discusses the influence of surgery on the development and evolution of diabetes He maintains that in all cases of suspected biliary infection search should be made for pancreatic dysfunction, that such cases require not only cholecystectomy, but also routine drainage of the common duct When this is performed the blood cholesterol falls rapidly to normal It is admitted that a rise in blood cholesterol indicates obstructed biliary drainage, or, in the absence of obstruction, is an index of the progress of the diabetes

308 Acute Pancreatitis

E L ELIASON and J P NORTH (*Surg, Gynecol and Obstet*, August, 1930, p 183) consider that acute pancreatitis is not a rare condition, and that its increasing frequency, high mortality of at least 50 per cent, unknown etiology, and high index of incorrect diagnosis, with the doubt about its proper treatment, render it important in the differential diagnosis of abdominal affections Reported cases show slight preponderance in the female sex, with an almost uniform age distribution throughout the third to the sixth decade Associated biliary disease was noted in two thirds of the cases The authors remark that although acute pancreatitis may arise without any warning symptoms the great majority of cases must be regarded as extensions of pre existing biliary tract infections such as chronic cholecystitis In not more than one third of the reported cases was a correct diagnosis made before operation, the protean manifestations simulating acute cholecystitis intestinal obstruction, perforated ulcer, and acute appendicitis, the true condition was only revealed at operation by the peritoneal exudate mixed with blood, and the fat necrosis Vomiting is a constant symptom, and is marked in the fulminating hyperacute cases In about 40 per cent there is a pathognomonic slate grey cyanosis of grave prognostic significance, it is limited to the upper portion of the body An immediate laparotomy is considered to be the proper procedure by most American and European surgeons, though some Danish surgeons favour expectant treatment From their experience the present authors advocate deferring the operation until after the acute phase, unless indications arise necessitating immediate intervention, the risk of early operation is increased by the incidental complications, but accuracy in diagnosis is essential to the adoption of expectant treatment

Therapeutics.

309 Hot Baths in the Treatment of Multiple Sclerosis

MEHRTENS and Pouppirt have reported the results of employing hyperpyrexia in various nervous diseases, and concluded that neurosyphilis offers the most favourable field for such treatment, the benefit being as good as that obtained by malaria therapy Kahn and Steiner found a spirochaete in some cases of multiple sclerosis, and more recently Chevasut has described the detection of an extremely small organism, which is easily killed by heat, in the spinal fluid of patients with that malady From these facts F G LINDEMULDER (*Journ Nerv and Mental Dis*, August, 1930, p 154) deemed it reasonable to try recurrent elevations of temperature in multiple sclerosis, and he reports the effects of giving high temperature baths in twelve cases The patients were all placed on high calorie diets and were weighed daily Fowler's solution (5 minims three times a day) and elixir of iron, quinine, and strychnine (1 drachm three times a day) were administered during the series of baths A bath was given every second day, and in some cases daily, up to a total of eleven, the patients being immersed up to the neck in a continuous bath at 104° F for ten minutes The temperature was then raised to 110° F, and kept at this temperature for thirty minutes, after which a fall to 104° F was permitted, the bath was kept at this temperature for twenty minutes, the patient spending altogether one hour in the bath The patient was then removed and wrapped in woollen blankets, remaining thus for two or three hours or until the mouth temperature was normal The effects produced on the pulse respiration, peripheral blood, and weight are described Herpes simplex, which lasted five days, occurred in three cases, and was the most serious complication of the treatment, in female patients metrorrhagia was a common complaint Four patients showed decided improvement following the treatment, all becoming less ataxic, nystagmus disappeared in one, and a positive Babinski reaction in another Two patients seemed to be considerably worse, while the remainder showed no special change in symptoms Lindemulder draws no definite conclusions, however, as to the therapeutic value of hot baths in multiple sclerosis

310 Therapeutic Results in Essential Hypertension

BLING impressed by the numerous successes reported following the use of many different drugs and methods in the treatment of essential hypertension, D AYMAN (*Journ Amer Med Assoc*, July 26th, 1930, p 246) has made an analysis of thirty five articles dealing with the treatment of this condition On the basis of these reports he concluded that the symptoms are easily relieved, a more easy achievement than lowering the blood pressures, and that this symptomatic relief may be obtained by any of numerous drugs and methods It is not probable that each of these drugs has a specific action, and it is more reasonable to believe that there is a common and specific factor associated with their administration This common element Ayman conceives to be the enthusiastic giving or doing of something to the patient—that is, it is the treatment, regardless of its nature To test this theory 40 hypertensive patients with active symptoms were treated as follows A complete history of the existing symptoms was recorded and a physical examination was made, even though most of the patients had been in the clinic for months or years Thus the patients were at once impressed with the new interest manifested in them Then, seriously and enthusiastically, 10 drops of dilute hydrochloric acid were prescribed to be taken in half a glass of water fifteen minutes before meals three times a day This drug was selected because in drop dosage it certainly could not act with any specific power in the treatment of hypertension, and yet in such dosage it possesses an impressive taste Finally, the patients, all of whom were able to get about,

were told to return at weekly intervals Definite improvement was obtained in 33 (82 per cent) of the cases Two cases are recorded which illustrate the usual effect of 'treatment Ayman believes that the symptoms of essential hypertension may frequently be relieved by the suggestion inherent in any seriously and enthusiastically prescribed drug or method and that this is the probable explanation of many successes reported in the past

311 Collargol in Enteric Fever

NAGEOTTE WILBOUCHEWITZ (*Bull Soc de Péd de Paris* April, 1930 p 154) records fifteen cases of typhoid and paratyphoid fevers in patients aged from 7 to 50 and treated by the administration of collargol with beneficial results The symptoms were attenuated in each instance immediately after the treatment was started Headache disappeared in a few days there was no diarrhoea and the general condition was much improved The drug was given partly in a watery solution of 1 in 100 by the mouth in doses of 1 or 2 drachms four or five times a day and partly by injection of ten to twenty minutes duration with an ointment containing 15 per cent of collargol silver

Laryngology and Otology

312. Otitis Media in Infancy

G RIZZI (*Arch Ital di Otol Rhinol e Laringol* June, 1930 p 262) in the course of a year found 50 cases of purulent otitis media on one or both sides among 192 necropsies on children who had died within the first two years of life the suppuration in almost every case not being discovered until after death In 35 cases there was a mixed bacterial flora but in 8 there was present only a single organism which in 5 cases was the pneumococcus while in 5 the pus was sterile Of the children, 30 were suffering from acute respiratory affections 7 from diseases of nutrition or the blood 6 from meningitis (other than the tuberculous form), 6 from tuberculosis and 1 from septicaemia Rizzi maintains that suppurative otitis media is a very important factor in broncho-pneumonia and meningitis, in which the primary infection of the ear may be the true cause of death As regards diseases of nutrition, while it is impossible to be certain that infection of the ear is the chief cause of the child's loss of weight it is justifiable to suppose that a latent infection of the middle ear predisposes to a disorder of nutrition or aggravates one already present In tuberculous disease on the other hand the suppuration in the ear may be regarded as a secondary process

313. Indications for Complete Tonsillectomy

G POPTMANN and J LAPOUGE (*Rev de Laryngol, d Otol et de Rhinol*, July 18th 1930 p 445) regard the operation of complete tonsillectomy as being only within the province of specialists but summarize indications for the operation for the guidance of general practitioners who appear to favour the incomplete 'morcellement' operation The indications detailed are as follows (1) Recurrent attacks of acute tonsillitis in children especially when associated with enlargement of the cervical chain of glands and progressive impairment of health and also recurrent attacks in adults notwithstanding that the tonsils may be small or only consist of fragments left after 'morcellement' (2) Intratonsillar abscess, bursting into the crypts or through the surface This condition is often not recognized till the actual bursting of the abscess and gives rise to less pain than peritonsillar phlegmon (3) Peritonsillar phlegmon, which is always likely to recur unless tonsillectomy is performed The authors do not agree with the procedure of tonsillectomy in the acute stage as advocated by Barnes Basavilbaso and Bilancioni and emphasize the danger of a spreading streptococcal cellulitis A condition of pseudo-peritonsillar phlegmon sometimes leads to diagnostic error This originates from abscess formation between the anterior pillar and the ascending ramus of the mandible it is of dental origin, and most usually due to an infected wisdom tooth (4) Chronic tonsillitis, associated with infected crypts and either sclerosis or hypertrophy of the tonsil The main symptoms are fetor of the breath otalgia and tonsillar cough ' With regard to the last named it is stated that the usual cough reflex area is situated below the glottis but when a source of chronic irritation in the form of a septic tonsil exists in the very sensitive neighbourhood of the faucial pillars a new reflex area is established above the glottis The type of cough varies in infants and adolescents and in adults in the first two it is dry paroxysmal sometimes barking and often nocturnal in the second it is isolated and often alternating with rasping clearances of the throat Moreover, it tends to be less troublesome by night than in the daytime (5) Cervical adenitis where the 'tonsillar gland' and the cervical chain are chronically enlarged The authors would classify the febrile attacks occurring in subjects of cervical adenitis under the heading of "*glandular fever*" (6) Tonsillar mycosis clinically recognized by the presence of strongly adherent white patches originating from the crypts, and always recurring after local removal or cauterization (7) Diphtheria carriers should be treated by complete tonsillectomy when prolonged medical treatment has failed to eradicate the Klebs Loffler bacillus from the fauces The authors review briefly also the general indications for total tonsillectomy Among the conditions associated with tonsillar sepsis and sometimes improved or kept stationary by tonsillectomy are articular rheumatism acute and chronic endocarditis certain forms of anorexia and dyspepsia, and appendicitis the association of which with tonsillitis has been frequently noted in individual cases Nephritis is commonly a sequel of streptococcal involvement of the tonsil and where *B coli* infection of the uro-genital tract exists it is frequently secondary to damage by streptococcal toxins of faucial origin The authors hold that there is some evidence that tonsillar sepsis is a factor in the causation of goitre If sepsis exists tonsillectomy should be performed before the more radical operation of thyroidectomy is undertaken Encouraging results from tonsillectomy in cases of chorea have also been reported

314 Chronic Suppuration in Malignant Disease of the Accessory Sinuses

A J WRIGHT (*Journ of Laryngol and Otol*, August 1930 p 545) draws attention to the almost invariable association of chronic suppuration with malignant disease of the accessory nasal sinuses This may be regarded as secondary to the growth though it is possible that pre existing chronic suppuration is a causative factor in the production of the *malignant change* Wright is convinced that this is the case, and points out that a large number of cases of carcinoma of the ear follow an old standing chronic suppurative otitis He describes seven personally observed cases where the sequence of chronic suppuration followed by malignant changes is definitely established In the first case a mass of middle turbinate was removed from a nose which had been the site of extensive suppuration for many years This specimen was reported on by the pathologist as "pre carcinomatous The remaining six patients had long histories of chronic suppuration which had persisted in spite of many operations and was later discovered to be malignant Old standing suppuration as is shown in these cases tends to mask the diagnosis of malignant change before operation Wright thinks that his experience emphasizes the importance of making every effort to cure accessory sinus *suppuration*

Obstetrics and Gynaecology

315. Treatment of Post-operative and Puerperal Thrombophlebitis.

E LEIBHOLZ (*Münch med Woch* June 13th, 1930 p 1017) reports good results from the ambulatory treatment of phlebitis by plaster bandages His method is as follows The affected parts if still inflamed are painted with 26 per cent zinc oxide in olive oil or with ichthyol If the inflammation has subsided They are then covered with mull muslin, and next with a thin padding of cellulose bandage from the ball of the great toe as far up as necessary The most important part is the plaster bandage, this is impregnated with zinc and glue and is applied under slight traction so that it compresses lightly the padding and reaches from the ball of the great toe to the border of the calf For the knee and thigh a tubular tricot bandage is used and attached to the skin of the thigh with leucoplast The outside layer is always mull muslin, this prevents stretching and provides resistance to changes in size which is an important factor in healing This treatment may be begun after fomentations and rest in bed or immediately on the onset of an acute inflammation or when the condition is not improving under fomentation treatment It is specially indicated in the case of patients who are otherwise ready to get up The author states that he has treated 185 cases of phlebitis of the saphenous veins very successfully There was no case of embolism pain had ceased not later than the third day and acute inflammation by the fifth A few patients were kept in bed for as long as a week but many went back to work at this time He then turned to surgical phlebitis (post operative puerperal, or caused by tumour growth), and treated 50 cases one of these was associated with a small pulmonary embolism, but a good recovery ensued In 33 cases the saphenous vein was affected six of these patients had complications such as mastitis which kept them longer in bed,

the remainder got up as a rule on the sixth or seventh day, and were discharged from hospital on the eleventh or twelfth One case of phlegmasia alba dolens was treated with success, and 12 cases of phlebitis of the femoral vein, but not quite so favourably, the pain being more obstinate and there being more tendency to oedema, so that the average duration of treatment was 29 4 days The average duration of treatment for all surgical cases was 7 days raised limb and fomentations, 3 5 days of bed with plaster bandage on, and 6 days up in hospital, altogether 16 5 days Comparing these figures with those treated by the classical method, Leibholz claims for his method a saving of 60 per cent days as regards hospital beds

316 Trichomonas vaginalis as a Cause of Vaginitis

ALTHOUGH only scant mention has been made of *Trichomonas vaginalis* as a pathogenic organism until recent years, H D FURNISS (*Amer Journ Obstet and Gynecol*, July, 1930, p 93) believes that, with the exception of gonorrhoea, most leucorrhoeas are due to this organism, especially where the discharge is the result of inflammation of the vagina Only rarely has this parasite been found in the cervix, since the alkaline secretion is inimical to it Although his report deals only with thirty five cases, Furniss states that he has seen many more Age appears to be of no significance, the ages of the patients ranging from 12 to 60 The history indicated that six started during pregnancy Of the patients, 24 were married and 11 single, of whom 3 were undoubtedly virgins Three patients were known to have had gonorrhoea, and one had the double infection at the time of the first examination The duration of the disease was from one week to eleven years, the majority being of a few months' duration The onset was usually acute Some had only slight discharge and moderate irritation, while in others there was profuse discharge with vulval inflammation, at times there was superficial ulceration in the vagina Three patients had marked dyspareunia The best treatment was found to be a simple 1 in 4,000 bichloride of mercury douche, given twice a day for the first week, and later once daily The douching should be continued during menstruation, at a temperature of 100° F Only occasionally was a weaker solution necessary, and in no instance was there any evidence of mercurial poisoning Furniss states that the relief of symptoms is prompt, the organisms disappear quickly in from three to five days, reinfection is rare, and, should it occur, relief can be again brought about

317 Symptomless Rupture of the Pregnant Uterus

W R PAYNE (*Med Journ and Record*, July 16th, 1930, p 57) reports a case of symptomless rupture of the pregnant uterus in a woman, aged 25, who had had Caesarean section performed a year previously through a supra umbilical incision, the uterus having been incised posteriorly through the fundus The pregnancy now reported was carefully watched, and within two weeks of term a low midline incision was made under spinal anaesthesia and the child delivered through a lower segment two flap transverse type of section After closure the uterus was rotated forward and the fundus examined, when a perforation admitting the index finger was found at the uppermost angle of the old scar This appeared to be an old tear, since a sacculation the size of a small egg had formed over the opening as if the membranes had protruded through As there was no sign of infection the old scar was excised, and the patient made an uneventful recovery There had been no complaint of pain at any time before the operation, but on close questioning afterwards the patient described a slight intermittent twinging pain over the fundus for some days, it was at no time severe enough to cause her to seek advice The author concludes that the case shows the necessity for careful observation in dealing with a pregnant woman who has had a Caesarean section, since perforation of an old scar may be slow and practically symptomless

318 Intussusception of the Fallopian Tube

A PISTUDDI (*Ann di Ostet e Ginecol*, May, 1930, p 510) describes one personal case and refers to another one of intussusception affecting the Fallopian tube In his case subtotal hysterectomy was performed for uterine myoma in a woman aged 45, who had had painful menstruation since a febrile abortion fifteen years previously and menorrhagia for three years One centimetre of the left Fallopian tube exhibited an invagination, the distal portion of the ampullary extremity being infolded in the proximal portion The intussusception was chronically fixed, and microscopically there were distinct signs of old standing inflammation In the other case described by GOGOBERIDSE (*Zentralbl f Gynäk*, 1929 No 35), an intussusception was observed in a tube which was the site of a freshly ruptured tubal pregnancy

Pathology.

319 A Special Medium for Isolating Streptococcus epidemicus

I PILOT, B HALLMAN, and D J DAVIS (*Journ Amer Med Assoc*, July 26th, 1930, p 264) describe a culture medium which strikingly brings out characteristic colonies of the *Streptococcus epidemicus* of septic throat To a 2 per cent meat infusion agar (pH 7 2) defibrinated human blood and ascitic fluid are added in proportions of 0 5 c cm of blood and 2 c cm of ascitic fluid to 10 c cm of agar This mixture is inoculated with the material under investigation and poured into Petri dishes The best results are obtained when one or two dilutions are made, the colonies appear discrete, and not too crowded Ascitic fluid with a specific gravity of 1 01 to 1 016 from five different patients gave uniform results, horse serum may be used, but is said to be less satisfactory Defibrinated blood of the sheep or horse may be substituted for human blood The minimum proportion of ascitic fluid that will bring out the large colonies is 1 c cm of fluid to 10 c cm of agar On this medium in poured plates, *Streptococcus epidemicus* forms in the deeper parts as elliptical or thin lens shaped colonies surrounded by a clear zone of haemolysis On the surface the colonies become very large, at first they are moist, transparent, and biconvex, but later they flatten out, grow more opaque and grey, and become wrinkled and dry in the centre On the bottom of the plate the colonies spread out to form a large grey colony, which is homogeneous except for a small opaque nucleus In deep tubes similar elliptical colonies appear in the interior of the medium, on the sides of the tube the colonies spread out to form large, thin grey patches On the same medium the ordinary haemolytic streptococci and those of scarlet fever and erysipelas form small biconvex colonies that may become flat From the plates containing *Streptococcus epidemicus* moist preparations of the colonies in indian ink reveal distinctly encapsulated streptococci, an additional distinction between these and other haemolytic streptococci This medium has led to the ready recognition of human carriers and of inter-epidemic or sporadic infections by this organism

320. The Blood Picture in Scarlet Fever

J CHALIER, G PALLOT, and ROMAN MONNIER (*Journ de Med de Lyon*, June 5th, 1930, p 353) examined the blood of forty scarlet fever patients During the first four or five days the examination was made daily, in the following week three times, and twice in the week after that, so that 12 to 16 examinations were made on each case They conclude that leucocytosis is constant throughout the disease, ranging usually from 12,000 to 22,000 per c mm Neutrophil leucocytosis is an early manifestation which is transient and keeps within moderate limits The initial diminution of the mononuclears affects the lymphocytes only, the moderate sized mononuclears being normal in number or in excess There is a definite eosinophilia of 6 to 10 per cent, which, as a rule, is more marked during the period of invasion and eruption, but does not disappear at once, and the present authors have known it persist for at least twenty five days The characters of the eosinophilia may help in the diagnosis of scarlet fever from scarlatiniform eruptions in diphtheria patients due to serum, in them the eosinophilia is inconstant, less marked, and very transient

321 Etiology of Mexican Typhus Fever

M R CASTANEDA (*Journ Exper Med*, August 1st, 1930, p 195) discusses the etiological significance of the small Rickettsia like bodies described in the scrotal swellings by Mooser In a series of experiments on guinea pigs the present author has demonstrated that a scrotal swelling can appear in guinea pigs directly inoculated from a human case of Mexican typhus fever In certain strains obtained from different patients a number of generations of guinea pigs may show absolutely no scrotal swelling, but this may reappear in subsequent animals, suggesting though not absolutely proving, that the scrotal swelling is an integral part of the disease and not due to an incidental accompanying organism If the latter hypothesis was correct moreover, the organisms that caused the scrotal swelling might be expected to disappear during the negative generations An attack of typhus fever sustained by a guinea pig without scrotal swelling protects against the swelling upon subsequent inoculation, even when a strain is employed which produces this swelling with considerable regularity Louse passage increases the capacity of a strain to originate the scrotal lesion, probably because of the considerable accumulation of Rickettsia in the louse Castaneda believes that his experiments tend to prove that the swelling is a part of the disease and that the Rickettsia like organisms have etiological significance

NIGHT OR MORNING?—

WHEN TO TAKE LAXATIVES

There can of course, be no universal rule as to the taking of laxatives Circumstances vary and only the physician is in a position to judge their relevance But experience seems to show that a good deal of harm is often done by the common habit continued over long periods of taking aperients at bed time At night the colon is normally much less active than in the day and it seems unwise unless special reasons exist, to stir it to unwonted activity during the hours which should be allotted to sleep It is probable that much insomnia and many rest-disturbing dreams have their origin in the taking of a nightly purgative.

When there is an habitual tendency even to slight constipation not fully remedied by diet and exercise, it is suggested that the most satisfactory result can generally be obtained by the taking *first thing in the morning on an empty* stomach of a simple refreshing saline draught, such as Eno's Fruit Salt" provides Eno is a saline effervescent of fine granular consistency, containing no trace of irritating mineral salts such as Epsom and Glauber Owing to its purity and texture, it is agreeable to the palate its pleasantness owing nothing to added sugar or flavouring matter from both of which it is entirely free.

"The Doctor's Emergency Reminder"

The Proprietors of ENO's Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest of their series of "Medical Reminders"—with or without a bottle of their preparation as desired The Doctor's Emergency Reminder summarises briefly a few points in connection with the treatment of poisoning and various other emergency cases It is bound in black morocco limp to conform to the style of the previous publications in this series

J C ENO LTD, 160 Piccadilly, London, W 1

ENO'S "FRUIT SALT"

DEAF DOCTORS
AND DEAF PATIENTS

have proved "ARDENTE" a boon—a Heart Specialist whose work is so dependent on his hearing writes *"'Ardente' is a godsend to me"*, without "ARDENTE" he is, to all intents and purposes, "stone" deaf, with "ARDENTE" he carries on his work—what better testimony to "ARDENTE" merit?

Mr Dent makes a Stethoscope specially for deaf Doctors—the only one of its kind, which is widely used and praised Doctors whose work lies amongst the deaf prefer to prescribe 'ARDENTE' because they know that 'ARDENTE" is the only individual method in the whole deaf world (no mass production way can ever succeed with human disabilities) and they know what "ARDENTE service stands for to the deaf Many doctors who are deaf use 'ARDENTE

'ARDENTE' is entirely different and uncopyable and succeeds in widely differing cases A full range covers the needs of those suffering from varying forms and degrees of deafness and tinnitus Minutely adjusted to the requirements of the case for young middle aged, or old, and so sensitive as to have the desired effect even in middle-ear and nerve cases, bringing into action and stimulating the auditory system enabling it to function naturally and saving atrophy 'ARDENTE can be used or not at will and is sold under guarantee

ARDENTE is the choice of Doctor and patient—only after test and hearing or from prescription or particulars, is "ARDENTE" fitted, toned, tried, adjusted, supplied, and serviced.

Tests and demonstrations given at Doctors', patients' or our addresses, without fee or obligation

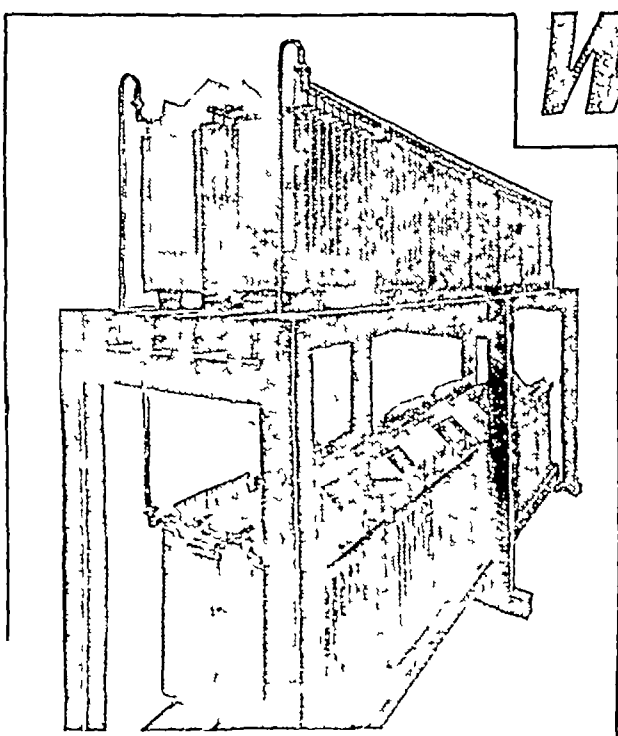
Your patients'
UNDERWEAR

There must be many times when patients consult you on the question of hygienic clothing.



There are soft Wolsey garments in every weight you would want to advise The value of pure wool underwear, which clothes the body lightly but warmly, we do not need to elaborate. But we may emphasise that in suggesting Wolsey you are recommending a brand of underwear with thirty years reputation

WOLSEY LTD, LEICESTER

WOLSEY *underwear*

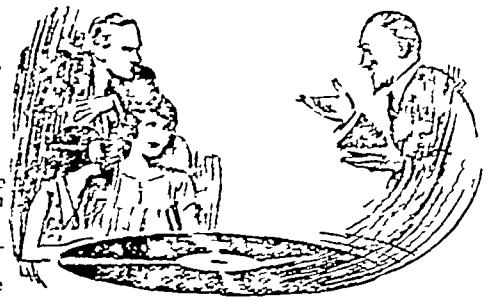
for women, men and children

When a life is at stake.....

The psychological moment has arrived Will the operation be successful? Can modern science triumph over such disease? The surgeon bends closer over the table deft fingers touching slender instruments a life is at stake if the lights should fail, plunging the theatre into darkness

Nowhere is reliable light supply more important than in operating theatres A light failure may have far reaching consequences Every hospital should be equipped with Ediswan Stationary Battery Then if current fails, a switch over to the Ediswan saves the situation and restores light almost immediately

The Ediswan Stationary Battery for Emergency Lighting is compact and robust It takes up little space and is sturdily built to give long service Running costs are almost negligible Installation costs are low



May we co-operate with you in evolving a Battery specially to suit your requirements?

First you listen, then—

You find yourself speaking FRENCH like a Parisian!

FRENCH or German Spanish or Italian Russian or Dutch—choose the language you would like to know and in a few weeks you find yourself speaking it fluently and with a perfect accent

That is the amazing thing about the new way of learning language—originated by the Linguaphone Institute—which has proved so successful that it is already being used by countless students all over the world and in over 2,000 schools and universities

SEE HOW EASY IT IS

You just sit down in comfort in your armchair and listen to a series of records on your own gramophone, spoken by expert native teachers

As you listen you follow in the illustrated Reader book the printed words that your teacher is using Very soon you become so sound perfect and word perfect that you are able to begin talking reading and writing quite fluently!

The correct pronunciation comes naturally—because you have never heard a word wrongly pronounced

The Holborn "TWIN PUMP" Operation Table.

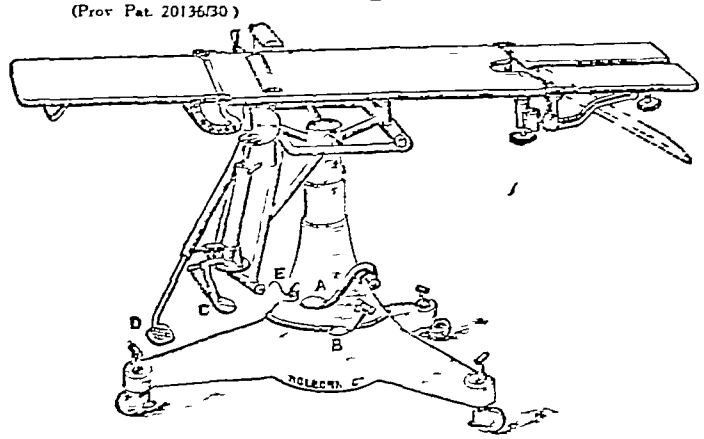
(Prov. Pat. 20136/30)

The only Operation Table on the market that can be tilted by the foot.

This table has all the advantages of an Oil Pump Table with the additional convenience of being fitted with a small oil pump and foot pedal by means of which the Operating Surgeon or Anæsthetist can tilt the table to the Trendelenberg position without interfering with the sterility of the hands.

A much easier movement is obtained with this foot pedal than is the case when a handle or wheel is employed

In the accompanying diagram—



A is the foot lever for raising the table from the base

B is the releasing pedal for lowering it.

C is the foot lever for tilting the table to the Trendelenberg position.

D is the pedal for automatically lifting the table to its original position.

E is the releasing lever for use when rotating the table

The Head and Leg Flaps are removable and the Kidney Bridge is built into the top of the table The head flap is lowered or raised by means of an improved "one hand" release, and the leg flaps are individually fitted with a screw adjustment.

The Base is mounted on strong easy running, castors which may be put out of action when desired All bright parts are chromium plated or Stainless Steel the pump and under carriage aluminium bronzed.

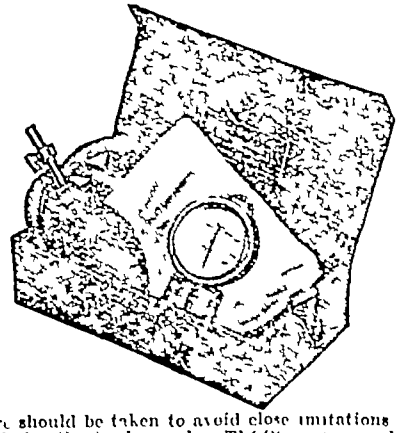
THE SALMON ODY SPIRAL SPRING ARCH SUPPORTS
The best Medical authorities are agreed that rigid plates are in various and are prescribing these supports for foot troubles—tired aching feet weak instops or rheumatic pains 15 6 per pair Metatarsal 18 6 per pair State size of footwear when ordering

Estab 120 years.

WHEN YOU PRESCRIBE WARMTH WITH FRESH AIR

All medical men will agree that the practice of heaping thick, stuffy fabrics on the body to keep out the cold is merely increasing the risk of winter chills and influenza The skin needs ventilation—the impurities in the air round the body must be allowed to escape Fresh air must have access Perspiration must be absorbed That is why Jaeger underwear, made of pure Jaeger wool, is so often recommended as the healthiest underwear for all seasons All Jaeger underwear is treated against shrinkage



YOU RECOMMEND JAEGER PURE WOOL UNDERWEAR!

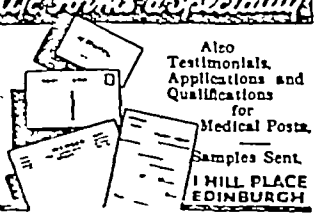
Accurate Arterial Pressure Readings

For visiting purposes the TYCOS Portable Sphygmomanometer amply fulfils the Physician's needs Although one of the most delicate and accurate instruments of the medical man's equipment the portable type as illustrated can be carried without fear of breakage There is no glass tubing to break no mercury to spill and the readings can be verified at a glance by comparing the relation of the hand to the immovable zero



Care should be taken to avoid close imitations Look for the trade mark TYCOS engraved on the dial of every genuine instrument

Obtainable from all reputable Instrument Dealers

THE POSTAL ACCOUNT

It is often supposed that to live a long way from the nearest branch of a bank or to be constantly unable to go to the bank in person is a handicap to the enjoyment of the full advantages which it is admitted a banking account offers Perhaps it is assumed that to conduct an account by post involves more letter writing or is costly or is not welcomed by the Bank It is the aim of the Westminster Bank to dispel such misconceptions by a leaflet entitled *The Postal Account*, which explains the convenience of the method and offers some clear suggestions

The Secretary of the Bank will be pleased to send a copy on application

THOS. A. GARNER, Secretary

Ministry of Health

APPOINTMENT OF DEPUTY REGIONAL MEDICAL OFFICERS

The Minister of Health invites applications from registered Medical Practitioners for appointment as Deputy Regional Medical Officer on the staff of the Ministry in various parts of England and Wales, for the discharge of combined clinical and administrative duties in connection with the National Health Insurance Medical Service

The rate of remuneration will be £800 per annum rising by annual increments of £30 to a maximum of £1 100 No cost of living bonus is payable in addition thereto

Successful candidates under the age of 50 years will be appointed to this scale and will be established Civil Servants with the usual pension rights Those who are considered to possess exceptional or special qualifications may be allowed to enter the above scale at a commencing salary of £850 per annum

Successful candidates of the age of 50 years and upwards (at the time of appointment) will be remunerated on the above scale and will receive unestablished non pensionable appointments In special circumstances where a candidate in this category has special qualifications and experience the commencing salary may be advanced to a point in the scale not exceeding £1,000 per annum inclusive.

Above the grade of Deputy Regional Medical Officer there are at present 35 posts of Regional Medical Officer (32 in England and 3 in Wales) rising to a maximum of £1,400 per annum inclusive and 4 posts of Divisional Medical Officer rising to a maximum of £1,600 a year inclusive The above numbers are however, subject to revision from time to time as the exigencies of the Service may determine When vacancies are to be filled among the Regional Medical Officers, preference will be given to those who have served as Deputy Regional Medical Officers

Candidates must be Medical Practitioners of not less than ten years standing and not exceeding the age of 55 years, with a wide experience of general practice, especially amongst the industrial population preference will be given to candidates who served in His Majesty s Forces during the war

Deputy Regional Medical Officers are required to devote their whole time to the Public Service and to perform such duties as may be assigned to them by the Minister from time to time These include acting as Deputy to the Regional Medical Officer in the work carried out by the latter

(a) as Medical Referee in cases of insured persons referred for a second medical opinion on questions of incapacity for work or of restoration of working capacity

(b) in assisting in the administration of the Insurance Medical Service.

Deputy Regional Medical Officers must be prepared to reside in the area from time to time assigned to them

Canvassing Members of Parliament or Officers of the Ministry will render a candidate liable to disqualification

MEDICAL BOARD FOR SILICOSIS

Under an arrangement between the Home Office and the Industries concerned the periodic and other medical examinations required under the Refractories Industries (Silicosis) Scheme, 1925, and the Sandstone Industry (Silicosis) Scheme, 1929, are carried out by a Joint Medical Board consisting of whole-time officers the members of which are allotted to certain centres and which has its central office at Sheffield The Home Secretary announces an immediate vacancy for a WHOLE TIME APPOINTMENT AS MEMBER OF THE MEDICAL BOARD The scale of salary is £750 per annum, rising by annual increments of £25 to £900

It is contemplated that in pursuance of the Workmen's Compensation (Silicosis and Asbestosis) Act, 1930, the present medical organisation will be extended shortly to certain other industries and processes, and that probably at least two additional appointments will then be necessary and applications for the post now vacant will, if the applicants so desire, be considered also in connexion with these further appointments

Further information and forms of application can be obtained from the Industrial Division, Home Office, Whitehall, London, S W 1 Applications should reach the Home Office not later than October 25th 1930 Recommendations or testimonials will only be considered if given by persons having personal knowledge of the candidate

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)

(Founded 1880)

12, Stratford Place,

Oxford Street, W.1.

Tele Address Triform, Wesdo—London. Telephone: Mayfair 1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION have every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads —

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

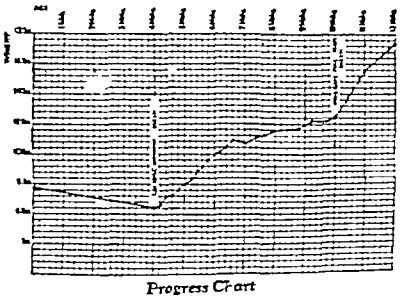
NATURALLY RICH IN VITAMIN "D"

A "RESURRECTION"

GUILDFORD
30 6 30



"Baby Hook, came under my care shortly after birth suffering with marasmus following whooping cough. Broncho-pneumonia developed and was with great difficulty cleared up, leaving the child in a very low condition. Feeding proved a difficult problem, several things were tried without beneficial results The results with Cow & Gate were truly wonderful, indeed it is a case of 'a resurrection.'"

(Signed)..... M.B Ch B

Lacidac (separated) and Brestol, the Cow & Gate Humanised Cream, were used in the early days of treatment. Cow & Gate Full Cream and Brestol being used subsequently.

BEFORE—4 months' old, 6 lbs. 9 ozs. in weight.

Progress Chart

AFTER—10 months' old, 12 lbs. 6 ozs. in weight.

June 1930 Baby Hook has now won a prize in a Baby Competition!

Write for literature and clinical samples of Lacidac and Brestol.

AMENORRHEA
DYSMENORRHEA

"It is a very great mistake to treat amenorrhea as though it were simply a lack of the catamenia, for it is a great deal more than that Behind this lack lies a cause It may be in the uterus or the ovaries, or it may be still farther back in the secretions of the endocrine glands or in the functioning of the vegetative nervous system"—("The Treatment of Amenorrhea," Dalché, *Revue Française de Gynecologie et d'Obstetrique*, May 1, 1920)

In the treatment of irregularities of the catamenia, rational therapeutic procedure is directed to the restoration of normal balance in the endocrine and vegetative nervous systems

Hormotone
BRAND

contains thyroid, pituitary, adrenal, and gonad substance, combined to take advantage of the demonstrated synergism existing between them In the treatment of these disorders Hormotone has been very successful

Dose One or two tablets three times daily.

INTERMEDIATE HOSPITAL IN ANNEXE AT 17, PARK LANE

Helped by an endowment fund, an Intermediate Hospital is now open for suitable general surgical cases at 17 Park Lane, London, W 1 The fees for a room cost now only two guineas a week, interest in the project having made possible a series of four reductions since the scheme was started

(The scheme is an attempt to help people unable to pay ordinary full surgical expenses and yet at the same time to avoid any semblance of a charity which would be distasteful to such.)

(The only condition attaching to the endowment is that any advantages—such as they are—should be widely advertised and not in any way limited to any small section of the community A further promise is made that if and as more beds are required they will be provided.)

All further particulars can be obtained from the Secretary or Matron at 17, Park Lane
Telephones Grosvenor 2312 & 2313

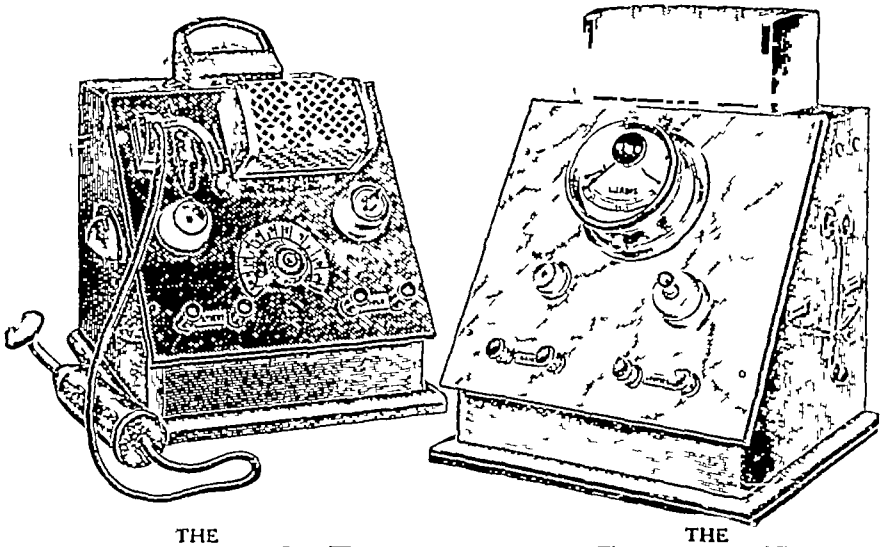
A Typical Scale of Reduced Fees for Surgical Cases in the Annexe Clinic of the Harold Fink Memorial Hospital at 17, Park Lane

Hospital Fees, including Nursing, 2 guineas a week (limited to an average stay of 3 weeks)	£6	6	0
Dressings, Theatre Fees, etc	1	1	0
Anæsthetic Fee	3	3	0
Surgical Fees for Major Operation (nominal fee only according to patient's means) .. (say, from)	10	10	0
(From Twenty guineas inclusive fee)	£21	0	0

The patient must be recommended as a suitable case for these reduced fees by their own Medical Attendant who may of course be present at the operation and who if convenient to himself will take charge of the after treatment while in hospital and be paid direct by the patient his usual fees for such attendance

When the patient's doctor wishes to arrange a preliminary consultation with the Surgeon in-Chief (with a view for example to a Bismuth Meal Cystoscopic X ray Examination etc) all that is necessary is to telephone either the Secretary or Matron and an appointment will be made (Proportionately reduced nominal fees only charged therefor) Telephones Grosvenor 2312 & 2313

All rooms are of course separate and hold one patient only there being no wards



THE PARK LANE PRIVATE HOSPITAL AND CONVALESCENT HOSTEL, LA CALIFORNIE, CANNES, AM FRANCE.

All particulars concerning fees, accommodation &c, can be obtained from the Matron, Miss ADAMS
Telephones Cannes 1452 and 2822

JUST ISSUED

ANDREWS'

JUST ISSUED

Diseases of the Skin

Books on Diseases of the Skin have lagged far behind the advances in the field of dermatology It has been Dr Andrews' aim to write a book that would fully cover all the important recent work in this field—to present the subject in complete, yet practical, form—and to visualise the text matter through illustrations that present a vivid picture of conditions as they are met in actual practice The author has endeavoured to include every point that may be necessary for the full understanding and management of each condition—all tests are detailed—all diagnostic procedures are described fully—and therapeutic measures are specifically given at great length

Illustrations are the very heart of a book on diseases of the skin—from their selection to reproduction An illustration short of perfection is of little value as a diagnostic aid Both author and publisher have realised this, and every effort has been made to select only pictures that truly portray the condition and then to reproduce them faultlessly The care taken has resulted in the creation of a veritable Skin Atlas—a masterpiece of the publisher's art

By GEORGE C ANDREWS A B M D Associate Professor of Dermatology College of Physicians and Surgeons Columbia University etc. Octavo of 1 091 pages with 933 illustrations Cloth 55s net

Maximow's Histology

Just Issued

Here is a new text book that presents histology from its *living functioning* and *human aspects* The student is told not that the kidney elaborates urine, *but which cells of the kidney elaborate which constituents of the urine—and by what mechanism.*

At all times Professor Maximow emphasizes the study of adult tissue, giving histogenetic data only where they will aid the student's understanding of the mature tissue or organ There are 604 striking histologic portraits! Not diagrams, but portraits of living material that will enable the student to recognise the structure when he views it under the microscope The proportions are accurate, the tones are life-like, and many show the relationship of cells in three dimensions They form a collection unsurpassed in medical art and are here brought complete to teachers and students for the first time

By ALEXANDER A MAXIMOW late Professor of Anatomy University of Chicago Completed and edited by WILLIAM BLOOM Assistant Professor of Anatomy University of Chicago Large octavo of 533 pages with 604 illustrations some in colours Cloth 40s net

Curtis's Gynaecology

Just Issued

This new text-book, by Dr Curtis, presents the successful methods of an eminent teacher-gynaecologist From his rich practical experience he has selected the subjects, determined the plan of presentation, and included those diagnostic and therapeutic methods which have proved their value

Each gynaecological condition receives a full and thorough discussion—a discussion that clearly projects the practical aspects Diagnostic features and technique are carefully described, including differential diagnostic methods where they are of value Important etiological and pathological features are pointed out Therapeutic methods are described with the same thoroughness and simplicity Dr Curtis gives the indications, special considerations, non-surgical methods, surgical methods, choice of operation, technique, radiotherapy, diathermy, and after-treatment

There are 224 illustrations by the eminent medical artist, Tom Jones They form a collection of pictures remarkable for their fidelity to life, especially in the demonstration of operative technique Many are of the vivid step-by-step variety, showing the progressive steps of entire operations

By ARTHUR HALE CURTIS M D Professor and Head of the Department of Obstetrics and Gynaecology Northwestern University Medical School Octavo of 375 pages with 224 illus 5 in colours Cloth 24s net

MODERN MEDICAL MONOGRAPHS

Designed specially for the practitioner

HEART DISEASE IN CHILDHOOD

by

H B RUSSELL, M D, M R C P, and
C K J HAMILTON, B M, M R C P

Demy 8vo 104 pages 7s 6d net

Heart disease presents special problems in the child, not only because of the difficulties in the diagnosis and management of cases of congenital heart disease but also—and a much more important reason—because it is in childhood that the acute infective phase of rheumatic heart disease most often occurs and on the treatment of that phase may depend the outlook of the patient's whole life

The authors have treated their subject in a lucid and most able manner, discussing the problems with which every practitioner has to contend, and explaining methods of diagnosis and treatment'—MEDICAL TIMES

This book will be warmly welcomed, dealing as it does with a subject which is engaging so much attention at the present time"—NURSING TIMES

MODERN METHODS OF FEEDING IN INFANCY AND CHILDHOOD

by

D PATERSON, B A, M D, F R C P, and
J FOREST SMITH, M R C P

Demy 8vo 162 pp Second Edition 7s 6d net

The first edition appeared in 1926, and has well established itself as one of the most useful and practical of the shorter books on this subject The second edition is larger by some 40 pages and contains additions which considerably increase its utility and completeness. These chapters are admirably clear and practical, giving definite indications of quantities required and stressing common dietetic errors such as excess of carbohydrate and of milk —LANCET

'It constitutes a very complete guide in all the difficult details of dieting a delicate infant —NURSING MIRROR.

'It will certainly prove to be a popular book because it is concise and dogmatic, and expresses opinions in an easily remembered fashion —BRITISH MEDICAL JOURNAL.

MODERN VIEWS ON DIGESTION AND GASTRIC DISEASE

HUGH MACLEAN, M D, D Sc, F R C P Second Edition 12s net

The present-day position of gastric physiology and pathology is here presented in a most lucid and able manner Professor Maclean emphasises the fact that intelligent treatment of gastric diseases must be based on physiological knowledge. In this monograph he also gives full details for medical treatment of duodenal ulcers, and proves that recourse to surgical measures is not generally necessary in order to bring about successful results

It is not surprising that Prof Hugh Maclean's volume entitled *Modern Views on Digestion and Gastric Disease* has rapidly passed into a second edition —BRITISH MEDICAL JOURNAL.

'It presents an excellent résumé of present day knowledge, and the author's experience enables him to give much practical advice on diagnosis and treatment. —PRESCRIBER

'The general reading of the book by practitioners of general medicine will greatly improve the standards of practice in the difficult subject of gastric disease.'—CANADIAN JOURNAL OF MEDICINE AND SURGERY

MODERN METHODS IN THE DIAGNOSIS AND TREATMENT OF GLYCOSURIA AND DIABETES

HUGH MACLEAN, M D, D Sc, F R C P Fourth Edition 12s net

Of the successful series edited by Prof Hugh Maclean of *Modern Medical Monographs*, the first by himself on Glycosuria and Diabetes was brought out in 1922, and is now in its fourth edition, a testimony to its popularity which almost absolves the reviewer from further comment —BRITISH MEDICAL JOURNAL

MODERN METHODS IN THE DIAGNOSIS AND TREATMENT OF RENAL DISEASE

HUGH MACLEAN, M D, D Sc, F R C P Third Edition 12s net

This extremely useful handbook is both scientific and thoroughly practical, and thus has rightly been recognized as a book to buy and keep at hand for reference and advice in emergencies. —BRITISH MEDICAL JOURNAL.

THE ENDOCRINES IN GENERAL MEDICINE

by

W LANGDON BROWN, M A, M D, F R C P

Demy 8vo 152 pages 7s 6d net

This little book is written primarily for the general practitioner, who will find in it an account of the endocrine system and its diseases presented in a form which should certainly be of service to them —LANCET

MODERN METHODS IN THE DIAGNOSIS AND TREATMENT OF PULMONARY TUBERCULOSIS

by

R C WINGFIELD, B A, M B (Oxon), F R C P

Demy 8vo 144 pages 10s 6d net

It is definitely addressed to the general practitioner, and in short compact dogmatic chapters it presents just the information and guidance which the average medical adviser will appreciate —BRITISH JOURNAL OF TUBERCULOSIS

BACTERIAL VACCINES AND THEIR POSITION IN THERAPEUTICS

by

LEONARD S DUDGEON, C M G, C B E, F R C P

Demy 8vo 96 pages 7s 6d net

This book should prove most helpful to all those who are interested in the subject. —BRITISH MEDICAL JOURNAL.

We can confidently recommend this handy and up to-date volume on vaccine therapy —MEDICAL TIMES

MODERN VIEWS ON THE TOXAEMIAS OF PREGNANCY

by

O L V de WESSELOW, M B, F R C P, and
J M WYATT, M B, F R C P

Demy 8vo 108 pages 7s 6d net

The authors have succeeded in collecting and presenting in a readable form the more important facts gained from recent scientific research and this book will certainly afford some guidance in the management of difficult cases —B M J

MODERN DIAGNOSIS AND TREATMENT OF SYPHILIS CHANCROID AND GONORRHOEA

L W HARRISON, D S O, M B, Ch B, M R C P L Demy 8vo 176 pages 10s 6d net

This is a handy volume written by an admitted authority on venereal disease. It deals with the clinical diagnosis prevention and treatment of syphilis, including a useful chapter on the management of syphilis, the general principles of treatment of gonorrhoea are clearly presented and modern methods of treatment lucidly described —BRITISH MEDICAL JOURNAL.

It gives a lucid and concise account of syphilis, chancroid and gonorrhoea in all their manifestations and with the sections on diagnosis and treatment no fault can be found To the busy practitioner who cannot overtake the modern literature it should be very useful —LANCET

A really remarkable achievement!

THE KOMPAK MODEL

SMALLEST . . LIGHTEST . . . HANDIEST

The result of years of specialized effort to produce a more compact instrument without sacrificing the absolute accuracy which our Medical Profession demands, and which they have always found in the Baumanometer

Compactly encased in Duralumin — inlaid with genuine, Morocco grain leather, weighing only thirty ounces — the Kompak model is not only lighter and more durable, but smaller in every dimension And it has our lifetime guarantee against breakage and the absolute accuracy guaranteed to all Baumanometers

For accuracy, portability, and simple beauty, the Kompak Model will undoubtedly commend itself to the Medical Profession Not only does it contain all the improvements pioneered by the original Baumanometer (of which more than one hundred thousand are now in use) but many others which you cannot begin to appreciate until you see them

Now on display at leading Surgical Equipment Houses, or at

A letter recently received

The Medical Adviser of
Messrs Kaylene Ltd,
London

Dear Sir,

The case to which I referred was a child of six months who was brought to me after having treatment elsewhere for diarrhoea and vomiting The child was practically a skeleton and apparently had been vomiting everything—even medicines—for many days The mother thought, and her friends thought, the child was dying, and I happened to be the nearest doctor I gave the child one teaspoonful of plain Kaylene in plain, cold, boiled water, and kept the mother and child in my consulting room to watch effects If ever a child was drawn from the jaws of death, I think that little sufferer was The Kaylene was retained, the gasping steadily lessened, the haunting look of that child's eyes became less distressing, in fact, the change for the better was so pronounced that in an hour's time I allowed the mother to take the child home

Fortunately, I had sufficient Kaylene by me (a sample you kindly sent), and I gave the mother sufficient to give a teaspoonful every hour during the night The chemists' shops were all shut by this time I gave full instructions—strict instructions—not to give anything else but Kaylene and plain, cold, boiled water as I had done

In the morning the mother came to see me and informed me that only twice during the night the child had loose stools but no vomiting, and had slept fairly well The child had other two loose motions during the day, but not offensive ones like all the other stools In the evening the child cried—the first time for two days—and as she looked, and was, so much better, I gave her some white of egg with plain, cold, boiled water Still improving, I kept her on this for three days She was doing well and I then allowed her milk She made a complete recovery, and there can be no doubt whatever that Kaylene saved the child's life

Yours faithfully,

M B, C M

Medisoap Therapy IN FACIAL SKIN DISEASE

Many patients object to the disfiguring effect of ointment in cases of facial skin eruption Medisoaps provide an effective alternative and the cumulative effect of regular application of the medicaments in this way will be found of great value

In severe and chronic skin diseases Medisoaps need not entirely displace other treatment The specimen formulae given below illustrate some of the ways in which they are used

MEDISOAP SULPH PRAECIP Nos. 4 9 and 19 — In Barbers Rash and similar diseases They relieve the irritation of Acne and are effective in the treatment of Scabies may be used in conjunction with Sulphur Ointment

MEDISOAP ICHTHAMOL Nos. 10 and 59 — Mildly antiseptic with a gentle stimulating action They are prescribed in cutaneous disorders generally and as adjuvants to other treatment

MEDISOAP TEREBENUM Nos. 91 — A winter antiseptic for the prevention of chapping Is excellent for personal use by nurses in cases of contagious disease

MEDISOAP HYDRARG BINIODID 5% 3% 1% ½% — Made with care to ensure the full proportion of the antiseptic and its accurate distribution throughout the base Is much prescribed for Eczema Psoriasis Ringworm and as a general antiseptic

MEDULLA RUBRA

BONE-MARROW IN ANAEMIA FROM HAEMORRHAGE

W Borchardt (*Deut med Woch* March 28th 1930 p 521) records the results of his experiments on young dogs in which anaemia had been artificially produced by the removal of about half their blood In the first series some of the animals were fed with rib marrow, others with marrow from the long bones Control animals received a corresponding amount either of fat or of liver extract. The basal diet in each case contained a sufficiency of iron (5 mg per cent) Only the animals receiving the red rib marrow showed a definite increase of weight, and their haemoglobin formation was more rapid than that of the others In the next series the experiment was repeated, but the iron content of the diet was reduced to 1 4 mg per cent) Only the animals receiving the red striking th dogs receiving the rib marrow regaining their haemoglobin far more quickly than the others

THIS extract from the "Epitome of Literature," published in the "BRITISH MEDICAL JOURNAL," dated May 3rd last, is important as representing, in 1930, a complete justification of the formula upon which

Roboleine
THE FOOD THAT BUILDS THE BODY

has been produced without variation during the past twenty-five years

The success of ROBOLEINE is thus due to intelligent anticipation and to consistently maintaining the highest possible standard of manufacture

Medical Practitioners are asked to satisfy themselves of the merits of ROBOLEINE, for which purpose testing samples will be gladly sent upon request

For Mother and Child

It is generally admitted that, if the physique of the next generation is to be improved special care must be directed towards the proper feeding of the expectant and nursing mother and of the child from birth to school age.

According to the teachings of modern dietetics the daily administration of an adequate supply of vitamins is of paramount importance

In prescribing Radiostoleum for the mother and child—whether in normal health or ailing—the physician is prescribing an accurately-standardised scientific preparation possessing one hundred times the Vitamin D activity and fully twenty times the Vitamin A activity of high-grade cod-liver oil

Radiostoleum, therefore, is a product of remarkable and unvarying potency, it possesses the advantage also accruing from its relatively small dosage.

Dimol

the Safe and Effective Intestinal Disinfectant

Before the discovery of Dimol the use of intestinal disinfectants was discredited owing to the impossibility of administering anything which was non-toxic to the host in the necessary dosage to produce the desired result

Dimol does not liberate phenol in its passage through the intestinal canal—it is not split up or absorbed, nor does it enter into combination with other drugs When it comes in contact with the pancreatic fluid it is emulsified and goes forward with the faeces and is voided unchanged

The dose recommended for Dimol is 2 to 4 pulverettes—say 3 Each pulverette contains 1 gr Dimol, and Dimol is 35 times more efficient as a bactericide than Phenol, that is to say, in administering 3 Dimol pulverettes the patient is receiving the bactericidal equivalent of 105 grains of Carbolic Acid.

After long and careful investigation at the Royal Naval College, Greenwich, Dimol Pulverettes are now being issued by the Admiralty for use in His Majesty's Ships and Royal Naval Hospitals

Dimol Laboratories, 40, Ludgate Hill, London, EC4.

ACCEPTED AMERICAN MEDICAL ASSN

B. COLI INVASION
of the
URINARY TRACT

cystitis, pyelitis, gonorrhoea, prostatitis, epididymitis, vaginitis, etc

PYRIDIUM—Phenyl-azo-alpha alpha diamino-pyridine hydrochloride—displays strong antibacterial properties toward coccal bacteria and B Coli It is of special service therefore in mixed infections and owing to its capacity for concentration in the tissues and organs of the genito-urinary system its beneficial effects are noted in addition to Cystitis and Pyelitis in such conditions as Prostatitis Epididymitis Vaginitis Urethritis Endometritis etc

Pyridium is administered orally in the form of 0.1 gram tablet — 2 t i d —and in its early excretion through the urine which it colours orange to red it exercises a soothing and healing effect on the mucous membranes Pyridium has marked power of penetration which explains its success in counteracting the ravages of cocci and bacilli below the surface and it also stimulates the proliferation of epithelial cells It is characterised by its freedom from toxic effects

Pyridium is the registered trade mark of The Pyridium Corporation of New York

Descriptive literature of Pyridium, together with sample will be gladly sent to any medical practitioner interested

Menley & James, Ltd, Hatton Garden, London

The Medical Profession when prescribing "Liquor Carbonis Detergens" SHOULD ADD THE WORD

Wright's

On receipt of your professional card a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap
Wright's Coal Tar Ointment
Wright's Lysol
Wright's Liquor Carbonis Detergens

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as an alcoholic solution of coal tar) the method of manufacture is unique Imitations will be found to be produced by simple digestion usually accompanied by some primitive perfunctory and inadequate stirring whereas in the case of the genuine product, the intimate contact required for the complete extraction of all the soluble antiseptic constituents is attained by a series of complicated processes involving the use of highly specialized machinery

WRIGHT, LAYMAN & UMNEY LTD, 66, Park Street, Southwark, S E 1

An Improved form of Treatment for Digestive Disorders

"Alocol" is the practitioner's safeguard when alkaline medication is required Its clearly defined antacid properties exceed those of bicarbonate of soda, magnesia and subnitrate of bismuth, furthermore, "Alocol" eliminates all the unpleasant drawbacks which are particularly feared with the usual alkalis and oxides

When "Alocol" reaches the stomach adsorption takes place, a colloidal jelly is formed which, adhering to the walls of the stomach, diminishes their sensibility The excess of hydrochloric acid is absorbed, but the acid reaction necessary for peptic digestion remains normal

"Alocol" is highly recommended for use in all cases of hyperacidity, against which it is a specific It is also indicated in the more serious manifestations, such as gastrectasis, gastrelcosis, pyloric and duodenal ulcers, etc

Complete chemical history of "Alocol" with convincing clinical reports and supply for trial, sent free to physicians on request

A. WANDER, Ltd, Manufacturing Chemists, 184, Queen's Gate, London S W 7

Works KING'S LANGLEY, HERTFORDSHIRE.

ALOCOL

Colloidal Hydroxide of Aluminium

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl salicylic acid possesses a notable disadvantage Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced

"Alasil" completely overcomes this objection By combining calcium acetylsalicylate with "Alocol," unfavourable secondary action upon the stomach is prevented This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract "Alasil" is therefore a triumph over acetyl salicylic acid It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time Analgesic, Antipyretic and Sedative, "Alasil" is indicated in all cases where acetyl salicylic acid has been used heretofore

A supply for clinical trial with full descriptive literature sent free on request

A WANDER Ltd, Manufacturing Chemists,
184, Queen's Gate London, S W 7

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate
May we, therefore, venture to remind you of

DINNEFORD'S
PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century and is still the best and safest means of administering Magnesia.

When prescribed for the nursery too, Dinneford's Magnesia has always proved immensely useful as a corrective and when mixed with infant's food it prevents many of the troubles which are due to acidity flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.
It cannot harm the most delicate constitution and is at all times a safe and effective laxative.
Manufactured in London for the past 100 years

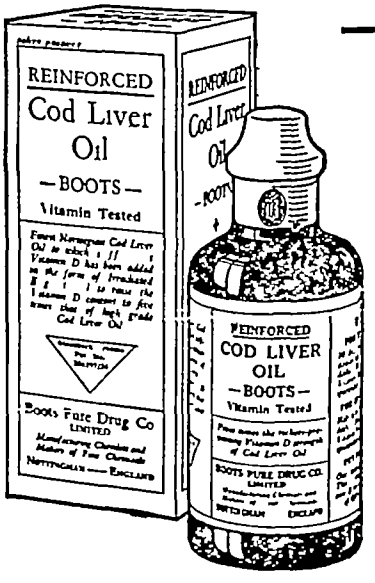
DINNEFORD & Co LTD

On the Absorption of Sanatogen

Why it is that Sanatogen is absorbed with ease even by the weakest stomach.

The tonic influence of the glycero-phosphoric-acid in the chemical combination casein-sodium glycerophosphate (Sanatogen) makes the use of casein possible in cases where the patient has to a great extent lost his capacity of absorption (Tunnicliffe, Tischer-Beddies, Chajes, a o)

French authorities (Robin and others) ascribe to the glycero-phosphates a great influence on the utilization of the albumin in the body The manufacture of Sanatogen is conducted under the strictest scientific control ensuring absolute purity, sterility and uniformly high dietetic value



Samples and Literature will gladly be sent on request to

GENATOSAN LTD, LOUGHBOROUGH, LEICESTERSHIRE.

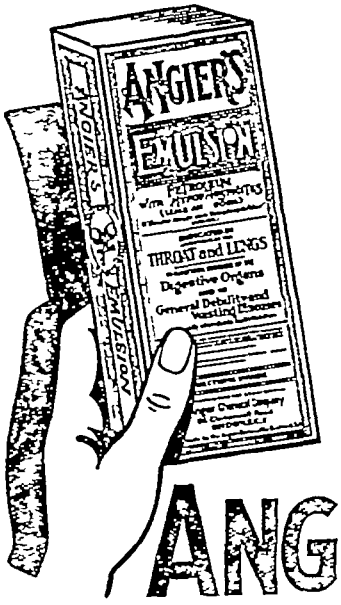
REINFORCED COD LIVER OIL —BOOTS



THE therapeutic value of Cod Liver Oil is fully appreciated by the Medical Profession It is recognised for its specific action (due to its high content of Vitamins A and D) in rickets, affections of the chest, and diseases arising out of *malnutrition* Boots Reinforced Cod Liver Oil is a biologically controlled preparation containing five times the amount of Vitamin D in addition to the normal amount of Vitamin A The advantage of a concentrated oil needing only a fifth of the usual dose will be particularly valuable Four fluid ounces of Reinforced Cod Liver Oil —Boots, contain the same amount of Vitamin D as one pint of the finest Norwegian oil

In 4-oz bottles, **2/6.**

Angier's Emulsion is one of the most useful and dependable remedies at the command of the physician for the treatment of the various inflammatory and bacterial affections of children Its soothing, inflammation-allaying properties and its general tonic effects are of first importance in these ailments, while its pleasant, cream-like flavour and ready miscibility with milk make it easy of administration even to the youngest infants

In many of the wasting diseases of childhood a sensitive irritable stomach and intestines preclude proper nourishment Under the administration of Angier's Emulsion these organs become pacified and retentive, digestion is strengthened, and the assimilation of food is normal and complete We confidently urge its trial in marasmus, scrofulosis, inherited tuberculosis, anæmia, and in the malnutrition associated with acute infectious disease

Sometimes a major operation...

YOU have many patients in whom coffee-drinking is a habit so consuming and so ingrained that prohibiting it is in the nature of a major operation on the patient's nervous system Without coffee, their appetite may be diminished, and the temptation to take a cup or two may be well-nigh irresistible

But now there is a pleasant, sure way to protect your patients from an overdose of caffein without prohibiting coffee good coffee rich coffee satisfying coffee—and that way is to prescribe H A G COFFEE

And that you may satisfy yourself how fully the effects of caffein have been minimized in H A G Coffee, make the night-test Send the coupon below for a liberal sample of H A G Coffee When it arrives, give it this convincing test drink your first cup of it at night It won't keep you awake Next morning you ll know, from actual experience, that patients can enjoy H A G Coffee without fear of caffein effect.

A perfect blend of finest coffees

H A G Coffee is all coffee—nothing but coffee —a delightful blend of the choicest Central and South American coffees The decaffeinization process takes place before the coffee beans are roasted, leaving undisturbed the spicy flavour, the fragrant aroma—everything that makes coffee "the beloved beverage"

This is scarcely less important than the fact that the effects of caffein have been minimized For, as you will discover, the delicious flavour of H A G Coffee transforms the order to give up coffee, because of its caffein, from a test of the patient's will-power into a daily delight

Your grocer stocks H A G Coffee—ground or in the bean and in vacuum tins that preserve its freshness and its fragrance Or send the coupon below for a liberal sample tin of H A G Coffee With it we shall be pleased to send a copy of "Some observations of the Action of Caffeine," a more complete discussion of H A G Coffee Send the coupon now

Remarks on THE INTRA-EPITHELIAL GROWTH OF CARCINOMA

BY

ROBERT MUIR, M.D., F.R.S.

PROFESSOR OF PATHOLOGY, UNIVERSITY OF GLASGOW

Carcinoma is usually regarded as an infiltration of tissue spaces and lymphatics by epithelial cells which have acquired the malignant neoplastic property. The essential neoplastic change, however, occurs first in epithelium which still has normal relationships to connective tissue, and the break through of basement membranes or other normal boundaries follows on the acquisition of malignant properties by the cells. This is well illustrated by the experiments of Murray and Woglom (1921), who showed that autoplastic transplantation of skin lesions produced by tar might be followed by growth of the transplant and infiltration before local infiltration could be recognized at the primary lesion. The amount of neoplastic proliferation which occurs before actual infiltration of the tissues varies much in different cases and the factors determining it can in great part be only conjectured, but in the case of the mamma what can be justifiably described as cancerous proliferation within the ducts may be of an extensive nature before invasion of the surrounding connective tissue occurs. Theoretically a skin epithelioma for example, might extend and destroy the epidermis without infiltrating the subjacent tissue but this is rarely seen: the break through into the tissue spaces occurs comparatively early. In other words, the connective tissue route of growth is preferred, we may say as offering least resistance. In certain conditions, however, free growth of cancer cells occurs within the substance of the epidermis and other epithelia, and this is the subject of the present communication. In discussing the conditions of occurrence, I cannot claim to bring forward anything new but I think that it may be useful to discuss the phenomenon in its various aspects especially as it has been little recognized by writers. I shall speak chiefly of the growth and extension of cancer cells in the epidermis, which may occur under three conditions.

1. The cancer cells may reach the normal epidermis by direct spread from an underlying growth, thereafter extending within the epidermis.
2. The cancer cells may reach the epidermis by continuous growth from the duct of a gland opening on the surface. The outstanding example of this is Paget's disease of the nipple occurring secondarily to intraduct carcinoma.
3. The cancer may start in the epidermis itself and spread within it, instead of infiltrating the subjacent tissue as is usually the case. In some apparent instances of this condition the point of origin may be in the skin appendages. I have illustrated these three possibilities by the diagrammatic sketches, the cancer is shown in black.

1 *Spread from Underlying Growth*

I have put first direct invasion of the epidermis by an underlying growth because it can be so definitely followed in this way we get a picture of how the cancer cells spread and what appearances may result. The occurrence in question is relatively uncommon, and has been described chiefly in connexion with the nipple. In most instances, when a cancer of the substance of the nipple reaches the epidermis, the latter merely becomes destroyed and ulceration follows, but sometimes the cancer cells penetrate the basal layer and gain a foothold in the epidermis, within which they behave like parasites. They flourish especially in the lower part of the rete malpighii, and may extend widely in a lateral direction from the point of entrance. Dilated cells may be detached and carried upwards to the surface by the growing epithelium: they undergo degeneration as they pass upwards, and ultimately only degenerated remains are seen, these being enclosed in capsule-like spaces in the horny layer. The histological changes thus resulting may correspond with those seen in Paget's disease, and cases of the kind we have described are sometimes included under this term. This, however, is unjustifiable, as in the condition of the nipple described by Paget there was no infiltrating cancer in the substance of the nipple, though a cancer often appeared later at some distance in the substance of the breast. The process of intra-epidermal growth of cancer has been described by Jacobaeus (1904) and others, including myself, but the most striking demonstration of its occurrence is that recently brought forward by Shaw Dunn (1930). In his case the growth was a mucin-forming (colloid) carcinoma involving the anal orifice and in sections stained by muci-carmine the cells wandering in the epidermis are brought out in a striking fashion owing to their content of mucin. The distribution of the cells in the epidermis and their extension over a wide area are clearly shown in the illustration given by him. Familiarity with the appearances thus brought about by what we may call infection of the epidermis is essential to the interpretation of similar changes which may be produced in other ways. The study of cases where the epidermis is directly invaded by an underlying carcinoma demonstrates what may result when the intra-epidermal type of growth becomes established. In cases of skin melanoma one may sometimes see isolated pigmented cells in the epidermis and this appears to me to be another example of malignant cells wandering in the substance of the epidermis (see also Jacobaeus, op. cit.).

2 *Spread from Duct Epithelium*

The invasion of the epidermis by cancer cells which have reached it by intra-epithelial spread from intraduct carcinoma of the upper ends of the mammary ducts, has already been fully described and discussed by me (1927), and I have little to add. The various stages of hyperplasia of duct epithelium ultimately culminating in malignant neoplasia, have been described by Cheatle (1926) and Charteris (1930), and with their accounts I agree in all essential particulars. One point which I consider of great importance is that in the early stages of the malignant change in the ducts the growth can be seen to be of the intra-epithelial type. The invading cancer cells spread in the epithelium of the ducts often leading to a layer of new growth of considerable thickness (this is fully illustrated in my paper referred to). Later the cells break through the surface layer and there results the more common appearance of masses of cancer cells filling the ducts. Intra-epithelial growth can also be observed in the acini and in a recent case I have found this occurring on an extensive scale. The intra-epithelial growth within the ducts and the acini is often seen to be widespread, and one must recognize that the disease may start in multiple foci of origin as well as spread directly. But I am of opinion that most of the characteristic features are due to the

Made in the Section of Bacteriology, Pathology, Physiology and Biochemistry at the Annual Meeting of the British Medical Association, Winnipeg, 1930.

latter factor Given, then, the fact that intra-epithelial growth of cancer is spreading within the ducts of the nipple, the question naturally arises what course the cancer cells will take when they spread upwards and reach the epidermis, with which the duct epithelium is continuous, and of which it is merely a modification The answer given by a study of Paget's disease is that the cancer cells continue to spread in the epidermis, and that they may do so over a wide area, there being an extensive lateral growth in the deeper parts of the epidermis The epidermis, however, offers more resistance to the growth of the cells, they multiply only in the deeper parts of the rete malpighii, and there apparently only with difficulty Nevertheless, the remarkable fact is that they may remain in the epithelium and show no tendency to pass again to the subjacent connective tissue The cells wander in the epidermis and many become degenerated, especially in the more superficial layers Hence the characteristic features of Paget's disease of the nipple result Such, in my opinion, is the sequence of events in the majority of cases I am interested to note that in a recent paper on Paget's disease, Simard, working in Masson's laboratory, has arrived at views similar to those which I have expressed As already stated, a corresponding histological picture arises when a carcinoma in the connective tissue invades the epidermis directly and spreads in it I also admit the possibility of the occurrence of an intra-epidermal growth from the cells of the epidermis itself, such as is met with in "Paget's disease" in other parts of the body (see below), but I have not met with a case of this

I may add that since my paper (1927) was written I have had the opportunity of examining seven additional cases of Paget's disease of classical type, there being no carcinoma infiltrating the connective tissue of the nipple in any of them In all of these cases the characteristic changes are present in the ducts, and in five of them direct spread of the disease from the upper parts of the ducts to the epidermis can be followed In four of the cases infiltrating carcinoma of ordinary type was present, deep in the substance of the breast In two other cases there were both intraduct carcinoma and also infiltrating carcinoma in the connective tissue of the nipple In these two cases it was not possible to state definitely by which of the two routes the cancer cells had reached the epidermis

In the illustration of one of my cases previously published, the Paget cells in the deepest part of the rete malpighii have assumed a somewhat columnar type, and this is more strikingly seen in one of my recent cases Not only can the spread of the disease be traced from the ducts to the epidermis, but, at places in the latter, a distinct line of columnar cells is seen resting on the cutis, while on their free surface there is a small collection of fluid which has raised up the epidermal cells These columnar cells may, in fact be said to represent a small metastasis from the intraduct carcinoma comparable to what occurs in a lymphatic gland only, in this case the metastasis has been produced by the wandering of the cancer cells by the intra-epithelial route

3 *Origin in Epidermis*

With regard to the intra-epidermal spread of new growth arising from the skin or its appendages I have comparatively little experience, but there is ample evidence of its occurrence There is first of all the Paget lesion occurring in extra mammary sites This is rare, but a considerable number of cases have been recorded (Susman) I am indebted to Dr Whitfield for a section from his case of Paget's disease of the vulva (1929), and in it I find a reproduction of the essential features of Paget's disease of the nipple so far as the mode of growth is concerned The cells are growing in clusters, especially in the deeper part of the epidermis, while isolated cells are scattered through the latter There is also a striking intra-epithelial invasion of the sweat glands The cells vary in shape, they are angular or stellate and are loosely arranged as if bathed in an intercellular fluid Some show a tendency to assume a columnar type It is not possible to state definitely the site of origin, but the characters of the cells suggest to me a glandular structure in the vulva rather than in the epidermis itself In other cases of similar nature the cells are of more indefinite character, and suggest the possibility of origin from the basal-cell layer If this were so, such a growth would represent a rodent ulcer (basal-cell epithelioma) spreading intra-epidermally A corresponding spread of prickle-cell epithelioma is of rare occurrence, but it has been described by Borst (1904), and an account is given also by Borrmann in the case of both epithelioma and rodent ulcer (1904)

Bowen's disease is another lesion which comes up for discussion in this relationship I have not myself had an opportunity of examining a case, but from the accounts given and from the illustrations it has seemed to me possible that it represents a carcinoma spreading laterally in the epidermis without infiltrating the tissues underneath I am interested to find that this view has been adopted by several recent writers—for example, Fraser (1928), Wise (1929), Eller and Anderson (1930) The lesion usually remains indefinitely in the epidermis, but occasionally an infiltrating carcinoma develops However, I do not wish nor, in fact, am I qualified to discuss in detail the nature of such skin lesions I wish rather to emphasize the general principle—namely, that malignant growths arising from the epidermis or its appendages may spread in a lateral direction within the epidermis instead of passing into and infiltrating the subjacent connective tissue Such intra-epidermal growth, meeting with resistance as it does, is usually of very slow progress, and the disease clinically is of a very chronic nature In the case of the epidermis, just as has been stated above with regard to the ducts of the mamma, the possibility of multiple foci of origin must be recognized as well as extension from a particular focus

Conclusions

When we consider the features of intra-epithelial growth of carcinoma and its results in the three conditions which have been discussed, we find that they present various points in common In the first place, as has been stated, the growth of the cancer cells in the epidermis apparently meets with considerable difficulty, and is accordingly relatively slow, in fact, it would appear that it is only in the deeper parts of the epidermis that active proliferation can occur at all The malignant cells are carried up in the process of normal growth of the epidermis and soon show signs of degeneration Further, even in the deeper part of the epidermis the growth is not always continuous, and it is not uncommon to find the cells scattered in the rete malpighii and sometimes spreading widely into the sebaceous or sweat glands The appearances, in my opinion, can only be explained by the view that the malignant cells wander in the epidermis, and this holds in all three conditions discussed above I convinced myself of the occurrence of the wandering of the cells several years ago from the study of Paget's disease of the nipple of the ordinary type, and it is still more convincingly demonstrated in cases of secondary invasion of the epidermis by an underlying carcinoma, as in Shaw Dunn's case When, as sometimes happens, resistance to growth is great, the cancer cells may be found only singly or in small clumps, and nearly all in a more or less degenerated condition Such cases are unsuitable for histological study and interpretation, and this fact is partly responsible for the great variety of opinions which have been expressed with regard to Paget's disease of the nipple In certain cases, however, all intermediate stages can be found between such degenerated cells and masses of cells which present the features of cancer cells and are undergoing active mitotic division

I have already indicated that the cells in the epidermis always appear to be growing in somewhat unfavourable surroundings, and another striking fact is that they are restrained in some way from breaking through the limits of the epidermis and infiltrating the cutis I have never, in fact, seen a clear example of re-passage from the epidermis to the connective tissue, although, of course, the possibility of its occurrence cannot be excluded But we can at least say that once the intra-epidermal extension of the growth has been established, the cells tend to be restricted to the epidermis

The presence of cancer cells growing in the epidermis leads to a definite reaction in the cutis There occurs new formation of capillaries, and this is accompanied by extensive infiltration of leucocytes and plasma cells, I have also met with eosinophils in large numbers When the growth within the epidermis is discontinuous, a definite relationship between the affection of the epidermis and the underlying cellular reaction can often be recognized Owing to the new formation of blood vessels and their congested state, and to a certain amount of exudate which soaks through the epidermis, the characteristic features of such lesions are produced Of course, at a later stage the affected epidermis may become destroyed, and then there is a red surface formed by granulation tissue

EFFECTS OF HYPERTONIC SALINE IN THE TOXAEMIAS OF LATER PREGNANCY *

BY

VICTOR JOHN HARDING, D Sc, F.R S (CAN),

AND

H B VAN WYCK, B A., M.D,

(From the Department of Pathological Chemistry University of Toronto and the Metabolic Ward Burnside Maternity Hospital Toronto General Hospital.

FOUR years ago the authors, in a paper entitled "Diet in the treatment of pre-eclampsia," advocated the use of salt-free diet [1] Such diets contained about 3 grams of chloride reckoned as sodium chloride, and are more usually nowadays, and more legitimately, called salt poor At the time the authors were particularly concerned in making clear that diets high in protein or in fat were quite innocuous to pre-eclamptics As a practical corollary it followed that ordinary mixed diets of protein, carbohydrate, and fat could be utilized, provided they were salt-free or salt-poor Not only were such diets innocuous to the pathological condition, but the patients showed marked clinical improvement In view of the number of factors concerned, however, we did not consider it legitimate to ascribe the improvement to the protein or fat in the diet Rest in bed and general attention to hygiene are such powerful factors in general clinical improvement that it required much stronger evidence than we possessed to conclude that high protein feeding or high fat feeding was beneficial

We were also interested in the effect of our observations upon theories of etiology Protein *per se*—if our observations were correct—could not play a part in the production of eclampsia Those authors who had ascribed the reduction in the incidence of eclampsia in Germany [2] during the war as due to a reduction of dietary protein could not in our opinion, have been correct That a dietary factor exists appears certain That the dietary factor is protein or even fat, is uncertain despite the popularity of the former supposition We may state in further support of our contention that since our previous publication we have given high protein diets, not to pre-eclamptics, in whom there might be a doubt that actual convulsions would occur, but to eclamptics, who, having responded to treatment with sedatives, were admitted to the ward for further observations We noticed no aggravation of symptoms, indeed, as previously, we found an improvement

The use of salt-free or salt-poor diets in the treatment of nephritis of the parenchymatous type is well known The influence of sodium chloride or sodium bicarbonate in definitely aggravating the symptoms of albuminuria and oedema in that condition is a matter of well-known clinical and laboratory demonstration The observations of our previous paper may have been open to the criticism that we were dealing with patients in whom the kidney lesions were of the parenchymatous type De Wesselow [3] has emphasized the occurrence of this type in the toxaemias of pregnancy

Since then, however, we have been able to reinforce our conclusions on the part played by sodium chloride by a series of further observations—namely, by the use of sodium chloride intravenously The use of hypertonic saline solutions has become very general in some centres for the treatment of post-operative paralytic ileus, either actual or threatened It is also a powerful dehydrating agent and diuretic In the treatment of eclampsia or threatened eclampsia one notices, too a tendency towards the use of intravenously administered dehydrating agents Lazard [4] has enthusiastically advocated the use of intravenous magnesium sulphate Titus [5] uses 50 per cent glucose solution though with a confessedly different object Mussey [6] recommends ammonium chloride by the mouth. A brief review of many of the older methods of treatment shows that some of the therapeutic agents removed water—for example, purging venesection, hot packs These were used frequently and often with success Their object was to remove toxin, but at the same time they removed body fluid Thus the use of hypertonic saline solutions might prove beneficial True it might produce or aggravate oedema in a case complicated by parenchymatous nephritis, but the symptom of subcutaneous oedema has never been considered as *the* dangerous one in an eclamptic or pre-eclamptic patient To relieve the symptoms of convulsions and high blood pressure with its attendant dangers of haemorrhage, would be well worth the cost of a little oedema

These latter arguments, valid as they may sound, are fallacious The use of hypertonic saline solutions in toxaemias of later pregnancy is harmful We present four cases one normal acting as a control, the other three being varying degrees of toxaemias though we feel some doubt as to the diagnosis in Case II

CASE I.—*Normal Pregnancy 0 Para 8 Months Pregnant Aged 19*

Date	Blood Pressure mm.)	Urine Albumin (mg. per 100 c.cm.)	Notes.
1929 June 6	123.64	0	Full diet.
" 7			"
" 8	120/58	0	"
9			
" 10	124 68	0	3.0 c cm. of 10% saline intravenous.
" 11	124 58	0	" "
12	114/50	0	Full diet.

The patient had been observed carefully in the clinic, and was normal. The intravenous saline was given on June 10th at 2 p.m. after the noon meal. She complained of thirst and was given chipped ice she took an ordinary supper On June 11th the intravenous saline was given at 11 a.m. and the patient fed on orange juice the remainder of the day Later in the day two fluid bowel movements occurred but otherwise no effects were observed.

* A paper read in opening a discussion in the Section of Obstetrics at the Annual Meeting of the British Medical Association, Winnipeg 1930.

CASE II.—*Possibly Mild Toxaemia 4-Para 8½ Months Pregnant Aged 22*

Date	Blood Pressure (mm.)	Urine Albumin (mg. per 100 c.cm.)	Notes
1929 March 15	155/92	50	Few pus cells in urine. Full diet. Pot. cit. 30 grains. Sod. bicarb. 30 grains. Two-hourly.
" 16	138/98	20	
17	128/90	20	
18	134/90	30	3·0 c.cm. 10% saline intravenous.
19	11 /90	10	Complains of nausea. Milk diet.
20	118/84	10	Headache. Milk diet.
21	118/84	20	Well. Milk diet.

The patient was admitted from the outdoor clinic as suffering from mild toxaemia. She had slight puffiness in the ankles and face, and a blood pressure of 150 mm. A trace of albumin was found. She improved at once with rest in bed. The intravenous saline given at 2 p.m., caused excessive thirst, and the patient complained of weakness. Chipped ice was given to allay the thirst. Nausea and headache were complained of on the two following days. There was no oedema. A successful medical induction was carried out the following week.

CASE III.—*Mild Toxaemia 1 Para 8½ Months Pregnant Aged 21*

Date	Blood Pressure (mm.)	Urine Albumin (mg. per 100 c.cm.)	Notes
1929 Feb. 26	140/90	200	Full diet
27	120/96	190	30.0 c.cm. 10% saline intravenous 2 p.m. Milk diet. Vomiting.
28	134/90	250	Backache.
March 1	150/110	450	Backache. Vomiting.
2	138/80	—	Labour.

The patient was admitted from the pre-natal clinic on account of irregular gain in weight, slight increases in blood pressure, and sudden albuminuria. A stillborn birth had followed a previous pregnancy. The patient felt perfectly well, there were no headaches nor oedema. When the intravenous saline had been given the increase in albuminuria was marked. The blood pressure, both systolic and diastolic, on March 1st was the highest recorded over a long series of observations. Labour was prolonged, lasting three days. The baby was normal. On March 6th the blood pressure was 130/90, and the albuminuria was 100 mg. per 100 c.cm.

CASE IV.—*0-Para 8 Months Pregnant Aged 17*

Date	Blood Pressure (mm.)	Urine Albumin (mg. per 100 c.cm.)	Notes
1929 Nov. 16	190/130	—	Admitted. One convulsion. No oedema. Stroganoff treatment.
17		900	Improved. Milk diet.
18	140/112		Salt-free mixed diet.
19	130/100	6·0	Feeling well.
" 20	150/ 10		
21	148 1.4		
22	134/104	500	
23	122/90	400	
24	120/98	350	
25	115/84	200	
26 a.m.	128/100	250	300 c.cm. 6% saline intravenous 9 a.m.
p.m.	135/115	375	
27 a.m.	130/115		3·0 c.cm. 10% saline intravenous 10 a.m.
noon	178/158		Headache. Epigastric pain. Vomited.
3 p.m.	160/120		Vomited. Face congested. No oedema.
6 p.m.	180/118		Seems a little improved.
9 p.m.	200/140		Convulsions. Stroganoff treatment. Strong uterine contractions. Labour 11 p.m.
28	130/93	800	Water only.
29	140/100		Milk diet.
30	130/93		
Dec. 1	130/100	200	Feeling well.

The effect of the intravenous saline solution on the blood pressure, albuminuria and general symptoms was very clear. A colonic irrigation preceding the labour was followed by a veritable deluge of fluid. The labour was very precipitate. The foetus was small and ill developed.

Two well-defined criteria for estimating the extent of a toxaemia of later pregnancy are blood pressure and albuminuria. Judged by these standards our observations divide themselves into two groups. The first, consisting of Cases I and III—where Case I is normal and Case II is a doubtful toxaemia—show no effect at all. Both patients had thirst, as would be expected in any normal individual. In Case I there were two fluid bowel movements, and the patient in Case II complained of nausea and headache on the two days following the injection. The elimination of salt and water by the bowel was in all probability the reason for the two fluid stools in Case I. The nausea and slight retching in Case II may be a variation of the same method of elimination which failed to relieve itself by the emptying of the bowels. The headache followed the intravenous saline and lasted two days. Judged by the major criteria of albuminuria and blood pressure, however, both cases showed no effect—indeed, Case II showed an obvious drop in pressure, despite the disturbance caused by the nausea and the headache.

Judged by the same two criteria Cases III and IV form another group. In both the albuminuria increased. In Case III the concentration of 450 mg. per 100 c.cm. urine was the highest noted throughout the whole period of observation. One of us had made fortnightly weighings and blood pressure and urinary examinations of this patient for a previous three months. Albuminuria and a slight elevation of blood pressure had been observed a fortnight previous and on their continuation the patient was brought into hospital. Just as a peak in the albuminuria was noticed after the intravenous saline has been given, so a peak in the blood pressure level was observed, both systolic and diastolic. It is to be noticed that vomiting was present in this case also, and persisted for two days. It is hard to escape the conclusion that the hypertonic saline had aggravated the toxaemia. In Case IV the conclusion is irresistible. The changes follow one another with such dramatic suddenness that we have no difficulty in distinguishing cause and effect. On admission she had high blood pressure, marked albuminuria, and one convulsion. These, together with the absence of any history of nephritis, her age, and primiparity, make a clear diagnosis of eclampsia. The convulsive stage was easily checked by sedatives. Rest in bed and a salt-free mixed diet rapidly reduced the albuminuria and blood pressure. The effect of 48 grams of sodium chloride given in two doses on the mornings of November 25th and 27th immediately changed the whole picture. The changes were possibly evident on the evening of the first day when the blood pressure and albuminuria increased over those of the three previous days. The changes at the end of the second day represented a return to the symptoms of eclampsia. The blood pressure reached 200/140. Headache, epigastric pain, and vomiting were present. There was a typical appearance in the facies of congestion and coarseness, but no definite puffiness or pitting on pressure was observable in any part of the body. By 9.30 p.m. three convulsions had occurred. Sedatives were administered at once, but the patient went into precipitate labour, and delivered a living child within an hour. The albuminuria also had more than doubled in intensity.

From the standpoint of practical therapy the results are wellnigh disastrous. We have, at present, no wish to continue our observation in this direction. In our very incomplete state of knowledge it appears fraught with too much danger to the patient, though the very acuteness of the disturbance brought about by an external agency possibly offers safeguards of its own, of which we are only dimly aware. We refer to the onset of labour. In both of the latter cases labour supervened shortly after the disturbance initiated by the saline solution. In both cases a living child was obtained. With birth, as is often the case in rapidly developing eclampsia, there was a rapid subsidence of symptoms and a return to a normal condition. There is, however, a definite negative value to our observations—namely, the contraindication of hypertonic saline solutions in post-operative work in pregnancy where there is any indication of toxaemia, unless the pregnancy is to be terminated simultaneously.

The observations recorded in this paper extend and reinforce those of our previous work on this subject. The

commonly occurring dietetic factor which can enter into the production of eclampsia or pre-eclampsia is sodium chloride. Other observers have emphasized the value of restriction of salt in the treatment of such toxaemias from the standpoint of kidney insufficiency. Eckelt in Germany, de Wesselow and Wyatt[4] in England, Bland and Bernstein[5] in America have advocated salt restriction from this standpoint. Stander[16] in his recent monograph recommends a salt-free diet if there is marked oedema. In our previous paper we were inclined to think that salt could play a part in the more fundamental changes connected with the toxaemia and suggested a possible value in salt restriction from the standpoint of pre-natal care. The observations recorded in this paper lead us to the conclusion that a high intake of salt taken at the right moment in a developing toxaemia will produce an albuminuria, an increased blood pressure and convulsions, in a short period of time. Such a picture represents a fulminating eclampsia. One hears often of cases in which a patient under good pre-natal care and with a normal blood pressure and urine develops convulsions within a week or a fortnight, or where a patient with a mild toxaemia, and under observation develops convulsions within twenty-four or forty-eight hour of an office visit, when no immediate danger was suspected. If such a patient has had in the meantime a generous meal in which meat is prominent the protein is promptly blamed. We would suggest a strict inquiry into the amount of salt taken with the protein and the usual accessories of a generous meal. Salt restriction in our minds, is a necessary part of pre-natal care. Protein is harmless. Bland and Bernstein claimed a diminution in blood pressure when their toxaemia patients were placed on salt-free diet. This followed a three-day period of ordinary hospital diet in which no diminution in blood pressure was observed. Three days after admission to hospital is a short time in which to observe a fall in blood pressure in a case of toxaemia even if it is accompanied by rest in bed. A week or ten days is not too short in many cases. Bland and Bernstein appear to realize the weakness of their position, for they endeavour to make the observations more equable by allowing the patients the liberty of the ward during the salt-free diet period. It is unfortunate that they did not reverse the order of their diets in half their observations.

In our previous paper we noted observations on the effect of sodium bicarbonate in a toxaemia of pregnancy. There was a recurrence of the oedema which had subsided on the salt-free diet, and a distinct rise in blood pressure both systolic and diastolic. At the time we did not wish to associate the rise in blood pressure with the sodium bicarbonate. We were more inclined to ascribe it to the nervousness of the patient herself, who had observed and knew the significance of the return of the oedema. In the light of our new observations the rise in blood pressure, following sodium bicarbonate administration in toxaemia of pregnancy may be as justly ascribed to the retention of the sodium salt as it is after the intravenously administered sodium chloride, though it is to the sodium ion, rather than the chloride or bicarbonate ion, that we attach importance.

Our observations, too, have a bearing on the general question of a relationship between chloride retention and hypertension as claimed by Ambard and his school. On this continent Allen[11] championed the beneficial effect of extreme chloride retention on essential hypertension. His first observations were not substantiated by all later workers,[12] and Allen[13] himself later realized that all classes of hypertension were not benefited by the restriction. The high blood pressure of the toxaemias of pregnancy, where functional rather than morphological changes are involved, would seem a much more promising condition in which to show the effects of a salt restriction.

From the standpoint of etiology we believe our results to be of value. It is impossible in the present state of our knowledge to separate the influence of sodium salts and water from either a physiological or a pathological point of view. Our observations in this and in the previous paper have shown a connexion between sodium chloride and convulsions, albuminuria, high blood pressure, oedema, epigastric pain, and vomiting in the toxaemic subject. All these are, or can be, symptomatic of eclampsia or pre-eclampsia. We cannot but fail to conclude that underlying a variety of symptoms lies a unity of disturbance—a water retention or a change in its distribution in the body. Zangemeister[14] has stressed the importance of observing the gains in weight during pregnancy and of suspecting any abnormally high gain as a sign of impending toxaemia. Englinger[15] judges his toxaemia cases by the Cl retention, the daily weight of the patient, and a measurement of the water intake and output. Holtermann[14] tests for latent oedema in pregnancy by Kaufmann's modification of Frey's diuresis test. Sudrow,[17] using Caleotti's method of measuring insensible perspiration, finds a very low output in toxaemias.

Our conception of the toxaemias of later pregnancy is a disturbance involving fundamentally a change in water distribution. This may be preceded or accompanied by a water retention showing itself in an abnormal gain in weight (Zangemeister). Once initiated, however, the disturbance may show itself in many ways: (*a*) epigastric pain and vomiting—the significance of an attack of "acute indigestion" as symptomatic of a toxaemia when occurring in later pregnancy has often been emphasized, (*b*) albuminuria—with a kidney lesion of the parenchymatous type or mixed, (*c*) hypertension—often present as the sole symptom or accompanied by a slight albuminuria, in pregnancy of middle-aged multiparae, (*d*) oedema—one of the commonest of symptoms, (*e*) convulsions—occurring by themselves these resemble epileptic seizures, and can only be distinguished by the fact of pregnancy and the absence of any previous history of epilepsy, (*f*) perilobular liver degeneration—not always present.[13] One, or many, or any combination of these symptoms may accompany the water disturbance. Herrick[19] has pointed out how the constitution or the make-up (possibly endocrine) of the mother determines the course of the toxaemia as it shows itself in successive pregnancies. In our opinion it is this maternal constitution which determines the appearance of one or any combination of symptoms.

We have referred to changes in water distribution as well as to water retention. An interesting case illustrating a relationship between oedema and high blood pressure has been referred to us by our colleague Dr. W. G. Cosbie who has kindly allowed us to make use of his notes. The patient had been under his care and routine observation from the beginning of her pregnancy and had been perfectly well until February 19th when she complained of a severe headache. The essential symptoms and observations are best given in chart form.

CASE V.—*0-Para. 5 Months Pregnant. Aged 31.*

Date	Blood Pressure (mm.)	Urine Albumin.	Oedema.	Notes
1929 Feb. 14	135	0	0	Well
19	150	0	++	Severe headache. Oedema in face and feet. Bed with salt-free diet.
„ 20	170	+	+	Milk diet only. Oedema less. No headache.
21	190	++	0	Severe occipital and frontal headache. No oedema. One hour after record of B.P. two convulsions. Modified Stroganoff treatment.
22	142	+++	++++	General anasarca.
„ 23	160		++	Oedema disappearing. Hot pack.
24	140	+	+++	Oedema returning.
25	150	++	+	Oedema disappearing.
„ 26	170	+++	+	Oedema very fair.
27	196	++++	0	No oedema. Uterus emptied.

The sudden onset of symptoms was marked by a moderate rise in blood pressure with a moderate oedema. In two days in spite of a salt-poor diet and a milk diet the blood pressure mounted to the convulsive level with a disappearance of the oedema. In twenty-four hours the blood pressure had fallen and given place to a massive general oedema. The treatment on February 21st included magnesium sulphate to ensure brisk elimination by the bowel. It was reasonable to suppose that the water in the oedema had

come from the cells, since little or none had been given by the mouth, and that the water in the cells had been responsible for the high blood pressure An opposite state of affairs would appear to have taken place between February 24th and 27th The oedema subsided and the blood pressure rose Apprehensive of further convulsions, the uterus was emptied on February 27th The increase in the albuminuria during the same period is also significant

Allusions are to be found in the literature to the similarity of the convulsions of eclampsia to those produced in animals by the continuous forced administration of water Rowntree and his co-workers[20] discovered and investigated this latter phenomenon and termed it "water-intoxication" It is characterized by a positive water balance, but this is correlated with an alteration in the sodium or base balance which results in a lowered amount of sodium in the plasma Recovery from "water intoxication" convulsions in animals is very rapid by the use of intravenously or intraperitoneally administered hypertonic sodium chloride solution The observations in this paper show a complete contrast in the action of hypertonic saline on eclampsia compared with "water intoxication" in animals Moreover, Stander, Eastman, Harrison, and Caddan[21] have shown an increased amount of base in the plasma of eclamptics This again is in contrast with the findings in "water intoxication" in animals It would appear that, despite a similarity of the convulsive states in the two conditions, and that changes in the water balance are probably involved in both, a clear distinction must be made McQuarrie,[22] in his recent studies on epilepsy, has drawn attention to its similarity with eclampsia, as well as "water intoxication" According to the author the use of urea among other measures acts as a preventive against the seizures of epilepsy Harding and Harris[23] have recently investigated the influence of urea solutions in "water intoxication" with negative results, and are thus inclined to dissociate it from epilepsy Whether urea will be of value in the treatment of eclampsia and pre-eclampsia remains to be seen

FRACTURES OF THE PATELLA.*

BY

R WATSON JONES, M CH ORTH, F R C S,

LECTURER IN CLINICAL ORTHOPAEDICS AND IN ORTHOPAEDIC PATHOLOGY, LIVERPOOL UNIVERSITY, HONORARY ORTHOPAEDIC SURGEON, LIVERPOOL ROYAL INFIRMARY AND BIRKENHEAD GENERAL HOSPITAL

MANY years ago a London woman sustained a fracture of the patella, John Hunter records how, after months of treatment, the knee-joint presented the dual problem of extension limited by powerlessness, and flexion limited by stiffness Two hundred years have elapsed, but we are still faced with Hunter's problem, the keynote of the treatment of injury of the extensor apparatus of the knee, whether it be an avulsion of the quadriceps, fracture of the patella, rupture of the ligamentum patellae, or separation of the tibial tubercle, is the restoration of extensor power without impairment of flexion movement

Although fracture of the patella was one of the first bone injuries to come within the scope of operative treatment there are still many differences of opinion Is operation essential? Should the bone be drilled and sutured, or is it sufficient to suture the quadriceps expansion? Which is the best method of bone suture, and the best suture material? Is splintage also necessary? When should movements be commenced? Is manipulation necessary?

Hitherto these questions have been considered purely from the point of view of bony union, but if our objective is not simply union of the fracture, but restoration of the joint to normal, and we also consider the recovery of flexion movement, different indications arise It may be true that immobilization of a normal knee does not cause permanent stiffness, but if a knee-joint is injured, and particularly if an arthritic knee-joint is injured, the inevitable penalty of prolonged immobilization in extension is some degree of permanent limitation of flexion It follows that fractures of the patella demand sufficiently firm operative fixation to render external fixation unnecessary, this is particularly true of the elderly patient Early movement is essential, and a bandage applied firmly enough to prevent haemarthrosis gives all the post-operative fixation required The actual date when movements are instituted must be governed by the success of the operative fixation It is my own practice to test this by flexing the knee before stitching the skin If the fragments are firmly held, assisted movement is commenced the following day If the fracture is comminuted and fixation imperfect, movement is deferred until the fourth week, and is preceded by gentle flexion of the joint under anaesthesia deep enough to ensure perfect relaxation of the quadriceps With a fully relaxed quadriceps manipulation is quite safe during the first four weeks Within that time the adhesions are still light, they offer no resistance, and give way by the mere action of gravity unaided by any pressure on the part of the operator On the other hand, I regard manipulation at any time between the fourth and twelfth weeks as very unsafe The fragments are not yet firmly united, and the adhesions are now so firm and resistant that even the strongest suture material is liable to stretch or snap and allow separation of the fragments Manipulation which is deferred longer than four weeks should be postponed until there is clear evidence of bony union of the fracture

Operative Methods

If the necessity for early movement is accepted it becomes obvious that operation is essential, that the bone must be sutured as well as the lateral expansion, and that the suture material must be strong Catgut and kangaroo tendon are not sufficiently strong, and silver wire is notoriously unsafe and liable to snap (Fig 1) Piano wire, on the other hand, is much less fragile, and its flexibility has the further advantage of allowing a knot to be tied My own preference is for an absorbable material, and thick, braided silk has many advantages It is extraordinarily strong, will withstand a much greater strain than the contraction of the quadriceps, and is sufficiently elastic not to snap, it can be secured in any length, is easy to work with, and can be tied in a knot which, owing to the roughness of the braided surface, will not slip Lange has shown that

* A paper read in opening a discussion on fractures involving the knee-joint in the Section of Orthopaedics at the Annual Meeting of the British Medical Association Winnipeg 1930

within twelve months it is entirely converted into living fibrous tissue

The method of inserting the suture is of considerable importance because the operation must not only prevent vertical separation of the fragment but must also restore a smooth articular surface and prevent tilting of one fragment on the other The patello-femoral joint is non-weight bearing but we know from the analogy of upper-

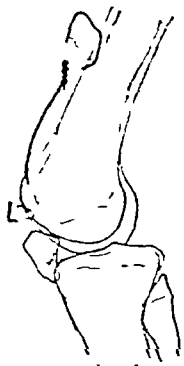

FIG 1

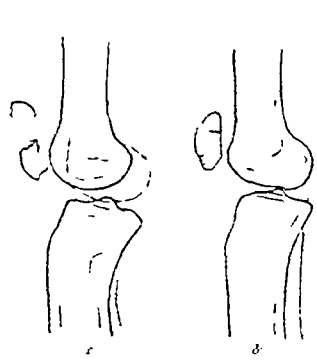

FIG 2.

FIG 1.—Old fracture of patella of rat 1 month after showing the fragility of silver wire The snapping of the wire has allowed wide separation of the fragments, complete loss of extensor power and secondary backward subluxation of the knee-joint

FIG 2.—Fracture of the patella the day before (*a*) and the day after (*b*) operation and fixation by silk suture Knee movement commenced the day after operation and in eight weeks there was full bony union and full flexion movement

limb joints that the constant movement of rough irregular surfaces will produce arthritic change, even in the absence of weight bearing Approximation should therefore be absolutely accurate by fitting the fragments carefully together not only is fixation augmented and union accelerated but osteo-arthritis is avoided For this reason the more quickly operation is performed the better, and the practice of delaying operation for ten or fourteen days to allow the absorption of extravasated blood must be relegated back to the days of unreliable asepsis I usually drill each fragment horizontally and use two pieces of thread passed in opposite directions so that they can be tightened simultaneously on either side of the bone This allows a much more accurate and close approximation than a single suture which is tightened on one side only (Fig 2) Accurate centring of the drill holes will usually prevent tilting of the fragment when the suture is tightened but if it is feared that tilting may occur during the early days of movement a square stitch may be used

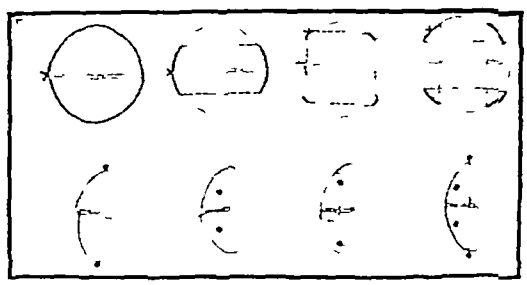

FIG 3.—Methods of suturing fracture of patella *a* and *b* encircling suture which may allow tilting of fragment *c* and *d* by a square stitch which ensures perfect apposition of articular surface

(Fig 3) in which the two horizontal strands prevent vertical separation, and the two vertical strand prevent tilting

After-care

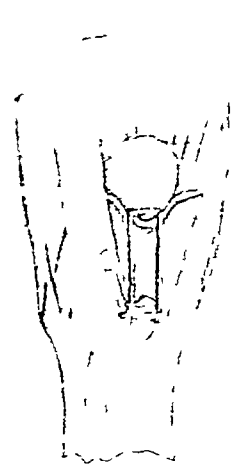
The objective of early movement demand rapid healing of the wound Forty-eight hours skin preparation complete screening of the skin at operation "no touch" technique and careful skin suturing are all essential The ∩ shaped incision should never be used I have seen three cases of sloughing of the apex of the inverted flap and apart from the risk of infection the joint is deplorably stiff has resulted from the scar tissue formation and the enforced immobility

Recovery cannot be regarded as complete until the quadriceps is fully redeveloped For this purpose the most complicated of gymnastic machines and of electric batteries cannot equal the patient's own efforts During half an hour of physiotherapy a masseuse may stimulate a quadriceps muscle fifty or sixty times What is that to compare with the constant contraction of postural tone? The valuable time of the masseuse should not be occupied in gently lulling the patient to sleep with massage but in vigorously goading him into activity, teaching him to regain his own mastery over the inactive muscle and showing him postural and resistance exercises which can be practised not for thirty minutes but for the whole of his ten or fifteen waking hours

AVULSION OF THE LIGAMENTUM PATELLAE

So far no reference has been made to the use of fascia lata and my own feeling is that it is an unsatisfactory suture material for the perfect approximation of two loose fragments not simply because it is difficult material to work with but because it is so elastic that early movement causes "springing" of the fragments, and one loses the perfect fitting together which operative treatment permits On the other hand it has an excellent application in the repair of avulsion of the ligamentum patellae from the lower pole of the patella

In this injury the intact patella is pulled away from the ligament and is displaced up into the thigh by the tonic contraction of the quadriceps It is notoriously difficult to suture the vertical ligamentous fibres to the bared lower pole of the bone which is held up in tension It may be quite impracticable and instead of suturing the patella to the ligament it must be anchored to the tibia in some other way The fascia lata already has a tibial insertion, and it is a very easy matter to take a strand from its thickened anterior margin still attached by one end to the tibia pass the other end through a drill hole in the apex of the patella and pull on it until the bone is down to its normal level The fascia may then be stitched to itself through a tunnel in the tibia (Fig 4) Sufficiently firm anchorage is given to the quadriceps and patella to allow repair of the ligament despite early flexion movement and provided that the patella is at a normal level perfect function results even although there is frequently extension of ossification into the upper part of the ligamentum patellae



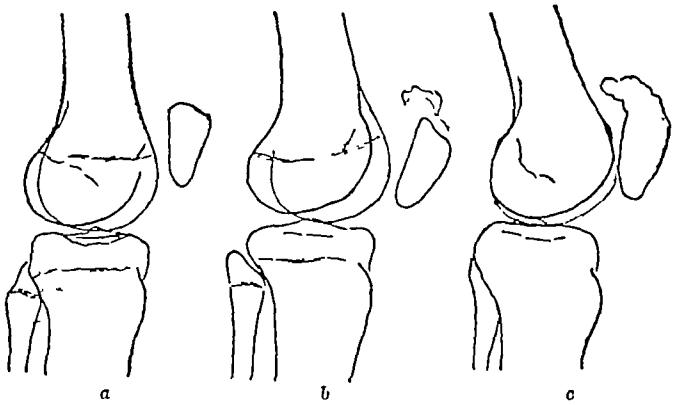


FIG 4.—Operation for repair of avulsion of the ligamentum patellae from the lower pole of the patella A strand of the anterior margin of the fascia lata still attached to the tibia is passed through the lower pole of the patella and tied to itself through a tunnel in the tibia

AVULSION OF THE QUADRICEPS

Exactly the same injury may occur at the upper pole of the patella, and the whole bone may be torn away from the quadriceps insertion The injury is not a common one and my own series includes only five cases of which one was bilateral It is frequently overlooked because at first there is no x-ray change The clinical signs however are exactly those of fracture of the patella and an even more serious disability arises in untreated cases

The injury involves mainly the inferior of the vastus internus and the crureus and the muscles detach the aponeurotic covering of the patella with an underlying layer of bone cell Within a few weeks new bone is

deposited, and, since the muscles retract, ossification may occur above the patella for two or three inches Subsequent *x*-ray examinations show gradual condensation of

a b c

FIG 5—Case of avulsion of the quadriceps treated conservatively by immobilization of the knee on a back splint *a* One day after injury *b*, Four weeks after injury *c* Two years after injury Despite immobilization, the quadriceps has retracted and its lower two inches is ossified. Better results follow immediate operative repair

the new bone and all the changes characteristic of myositis ossificans If the knee is immobilized in extension the new bone may remain attached to the patella (Fig 5), but if without first suturing the aponeurosis forced passive movements are carried out, the bone cells are still further separated from the patella, and large masses of free bone are produced (Fig 6)

FIG 6 — Untreated case of avulsion of the quadriceps with resulting ossification above the patella Note the resemblance to myositis ossificans

The term "myositis ossificans" of the quadriceps is an entire misnomer, the process is purely traumatic and mechanical, and in no sense inflammatory Far from being an inevitable complication of knee injuries, it is entirely avoidable by suturing the quadriceps back to the bone It must be equally true that many of the cases of myositis ossificans of the elbow are simply mechanical in origin, due to avulsion of the brachialis anticus, and preventable by securing reattachment of the muscle to the coronoid process, whether by conservative or by operative treatment

A MODIFICATION IN TRACHEOTOMY.

BY

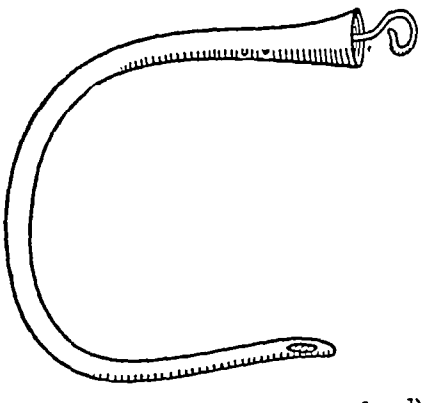
H G BEDFORD RUSSELL, F R C S,

SURGEON TO THE THROAT DEPARTMENT, ST BARTHOLOMEW'S HOSPITAL

My object is to place on record the application of a well-known manœuvre in a manner that does not appear to have been described previously

Progress in anaesthetic practice has made endotracheal catheterization a commonplace The work of Rowbotham and Magill[1] on the passage of the endotracheal catheter via the nasal cavities revealed unsuspected possibilities, and that of Magill[2] on the passage of the endotracheal catheter via the nose *without the assistance of vision* has further widened the application of this useful manœuvre

The introduction of endotracheal catheters via the nose, a proceeding that has proved most helpful in anaesthetizing patients with conditions such as trismus, has hitherto been performed after the induction of general anaesthesia, and it was obviously merely a matter of time before its potential advantages would point the way to the introduction of catheters via the nose under local anaesthesia The occurrence recently of a respiratory emergency in the throat department of St Bartholomew's Hospital provided an opportunity for the testing both of the possibility of the manœuvre and of its usefulness The history of the case is as follows



W D, aged 69 a big bully man with a short thick neck, was seen on June 24th suffering from severe dyspnœa with stridor, due to an intrinsic laryngeal carcinoma A satisfactory laryngoscopy was not achieved owing to the intolerance of the patient, and to the fact that alterations in the position of the head increased the dyspnœa to an alarming degree It was decided to perform a tracheotomy at once The shape of the patient's neck and the intensity of the dyspnœa rendered tranquil tracheotomy problematical, and laryngotomy was contemplated as being more practicable, at any rate as a preliminary General anaesthesia appeared to be contraindicated

It was thought worth while to try to intubate the larynx via the nose before actually beginning the incision, and after cocainization of the nose with a spray, the operator attempted the intubation, while the assistant held himself in readiness to perform an immediate laryngotomy if the intubation should fail A No 12 Porgès catheter mounted upon a stylet was successfully passed at the first essay, and after a short bout of coughing the delighted patient, speaking hoarsely round the tube, exclaimed, "This is pure Heaven! I'll remember it all my life"—not an overstatement, in view of his age and the condition from which he was suffering

A low tracheotomy was then performed in a leisurely manner, and with an entire absence of the anxiety which usually assails the patient (and not infrequently the surgeon) during an operation of this type on a cyanosed patient with a short neck The venous bleeding which might otherwise have been expected was noticeably absent It turned out that the tracheal rings happened in this man to be partially calcified, and that removal of the necessary piece was somewhat difficult—a fact which would probably have intensified the difficulties of tracheotomy by the ordinary method The coughing which usually follows upon the first perforation into the tracheal lumen was absent, because of the cocaine previously inhaled

DETAILS OF THE METHOD

It would seem that a great advantage in the nasal route is that while a patient suffering from dyspnœa is intolerant of any approach via the mouth, he does not resent the introduction of an innocent-looking tube into his nostril, and, provided the nasal passage and pharynx have been rendered moderately anaesthetic, he does not appear to be distressed by any groping for the larynx which may be necessary The anaesthesia is achieved quite quickly by spraying via the nasal passages (not the mouth) during inspiration with a solution of 10 per cent cocaine hydrochloride to which a drop of adrenaline 1 in 1,000 has been added, and the patient as a rule derives some immediate relief from the shrinking and numbing of the laryngeal mucosa While it is a fact that a tube passed via the mouth is more likely as a rule to find its way into the œsophagus, this seems not to be the case when the nasal route is employed The tip of the tube is usually tilted slightly forward by the cervical vertebrae, and so tends to arrive anterior to the opening of the œsophagus If the usual bulge forward of the cervical vertebrae is lacking, the catheter point can be bent forward upon the stylet so that it presents at the larynx

The diagram indicates the shape of catheter that was employed, but I gather that anaesthetists prefer to employ a soft rubber tube of large bore for routine use (upon patients already induced), relying upon the natural curve which is always present in such a tube, and upon small-range extensions and flexions of the patient's head to bring the tube opposite the glottis, so it may be that a soft tube might also be coaxed into the trachea even if stridor were present

POSSIBLE APPLICATIONS OF THE METHOD

The value of this procedure was striking in this particular case, and opens up interesting speculations as to the degree of its general utility It should be profitable to explore its possibilities in two distinct directions first, as

a preliminary to tracheotomy, secondly, as a measure in anæsthesia

It is important at the outset to make it clear that the manœuvre *does not call for special skill*. Magill has pointed out that provided the catheter is bent to the correct shape upon its stylet—roughly speaking a capital C—it is merely necessary to lubricate it and push gently, the operator being guided largely by the intensity of the respiratory sounds heard at the proximal end of the catheter. Certainly I have been able to endorse this dictum upon two out of the three occasions on which I have tried the manœuvre. In any case, the passage of a catheter is likely to be easier than the operation of tracheotomy, and in the event of failure the patient's chances with tracheotomy are not jeopardized.

In Respiratory Obstruction

I have not yet attempted intubation of the larynx via the nose in the obstruction of diphtheria, but, such cases for the moment apart, I would make a strong plea for an attempt at the passage of an endotracheal catheter as a regular preliminary to the operation of tracheotomy. If it is successfully passed, what was an emergency becomes a routine, and a step is at once taken towards the elimination of operative risks in tracheotomy. Further, if intubation has been achieved with cocaine, the way is now clear for an easy induction of general anæsthesia, if this should seem preferable to the use of novocain. If it should fail, neither patient nor operator is much worse off. It is possible even that cases of temporary obstruction may arise where this form of intubation may replace tracheotomy, as it sometimes does in diphtheria fever practice. This suggestion was made long ago by Dr. Magill, in a verbal communication.

For Anæsthesia in Throat Operations

The real bugbear of general anæsthesia at the present time is no longer the risk to life, but, to doctor and patient alike, is rather the risk of post-operative vomiting. While many anæsthetists are now accustomed to give gas and oxygen for tonsillectomy, provided the endotracheal catheter can be introduced after a preliminary induction with ether, the introduction of a catheter without the help of an ether induction or of the deep sleep afforded by paraldehyde—that is to say, under the influence of gas only—must be regarded as a great achievement. It is seldom therefore that the prospect of gas and oxygen anæsthesia throughout the operation enables us to promise the patient complete freedom from post-operative vomiting. If, however, the catheter could be introduced as a routine measure under local anæsthesia, throat operations could easily be performed under gas and oxygen anæsthesia only—that is to say, throat operations would be free from any risk of post-operative vomiting.

Before Emergency Tracheotomy

The case above described is one of two in which I have performed endotracheal intubation via the nose under local anæsthesia without the help of vision as a preliminary to tracheotomy, but upon three other occasions I have carried out intubation of the trachea as a preliminary to emergency tracheotomy, once with gas and twice with ether.

The first case was that of a woman whose trachea was obstructed by a large carcinoma of the thyroid gland. The operation of tracheotomy proved difficult even after the intubation, and would certainly have been a terrifying ordeal without it. In the second case intubation via the nose was done as a preliminary to tracheotomy in a case of tracheal obstruction of unexplained origin—possibly a retrosternal goitre—occurring during an operation upon the tonsils. It proved unnecessary to proceed to tracheotomy, normal respiration was restored on the patient's recovery from the anæsthetic when the tube was removed. The third case was that of a child aged 7 in whom the obstruction was caused by subglottic oedema following bronchoscopy for a foreign body. A little gas in this weak child sufficed to permit of intubation.

Conclusion

The purpose of this article is chiefly to put forward a proposal that tracheotomy should be preceded as a routine by an attempt at intubation of the trachea with a view to rendering the operation easier and safer of performance, and that the nasal route should be chosen rather than the buccal, whether local or general anæsthesia be employed. To this end it is urged that the tracheotomy set which should have a place in every operating theatre should comprise a catheter suitably curved upon a stylet with a spray duly charged with cocaine, and that students should be shown the manœuvre of nasal intubation—for example during their period of anæsthetic instruction. The acquisition of familiarity with this simple procedure should render a house physician's first tracheotomy a less alarming affair than it sometimes proves.

THE ETIOLOGY OF HIGH BLOOD PRESSURE

BY

R. C. WALTER, M.R.C.S., L.R.C.P.,

JUNIOR ASSISTANT PATHOLOGIST TO WESTMINSTER HOSPITAL

(From the John Lucas Cardill Laboratories, Westminster Hospital.)

A study of the published work on high blood pressure shows that many views have been put forward to account for its incidence. The following is a summary of the various factors which have been held to be implicated in its etiology:

1. Hereditary influence.
2. Infection (past or present)
   - (*a*) Generalized systemic infections
   - (*b*) Focal infections with dissemination of organisms
   - (*c*) Focal infections with dissemination of toxins
3. Intoxications (non-infectious)
   - (a) Exogenous (i) lead, arsenic, (ii) alcohol (doubtful), (iii) diet—excess of meat, general excess, condiment, constipation
   - (*b*) Endogenous
4. Metabolic
   - (*a*) Pregnancy
   - (*b*) Fatigue
   - (*c*) Endocrine disturbance

It is known that high blood pressure is in most cases accompanied by arterial or renal degeneration, it is also recognized that pathological degenerations are preceded by, and are therefore presumably the result of, some form of toxæmia. Hence it is not unreasonable to suppose that high blood pressure is the result of the action of some toxic body or bodies. Since it one of the chief functions of the liver to destroy toxic substances, it was considered that it might prove possible to show that the hepatic detoxicating functions are impaired in cases of hypertension.

On the assumption that high blood pressure is the result of a toxæmia, a considerable amount of work has been done in the past to establish the existence of a causative toxin, without its having proved possible to implicate definitely any one class of toxin and much less any specific toxic body. For the purposes of this present investigation the most promising field in which to search for a causative toxin seemed to be among the products of protein disintegration, since it is toxic bodies of this nature—for example indican—which are chiefly destroyed by the liver. The investigation therefore resolved itself into an examination of the products of protein metabolism and of the ability of the liver to deal with such product.

To this end full blood analyses with reference to nitrogen partition were made, the hepatic detoxicating functions

were judged in terms of the capability of the liver to destroy indican, and to combine drugs of the nature of salicylic acid with glycuronic acid, excreting them as the paired glycuronates The determination of nitrogen partition involved the estimation in the blood of urea, non-protein nitrogen, amino-acids, and purins It was anticipated that the presence of any non-protein nitrogenous toxin would show itself either as a relative increase of non-protein nitrogen over urea, or, if it should be of the nature of a specific amino-acid, it would naturally be found in this fraction of the analysis

In order to determine whether or not the liver was dealing with the metabolism of nitrogenous bodies in an efficient manner, estimations of the relative amount of ammonia nitrogen and urea nitrogen in the urine were carried out It is assumed that a normally functioning liver converts all but about 3 per cent of ammonia, produced as a result of deamination, into urea, so that a normal ammonia nitrogen to urea nitrogen ratio is in the neighbourhood of 1 to 60, and should not in any case exceed 1 to 35

Twenty-five cases of hypertension with systolic blood pressures varying between 185 and 300 millimetres of mercury, and twenty control cases in which hypertension was not present, were investigated The minimum, maximum, and average results in both series of cases are shown in the following tables Full experimental details showing the actual figures obtained in each individual case are available, and will be furnished on application to the author

Cases of Hypertension

	Minimum	Maximum	Average
Age in years	19	80	54
Systolic blood pressure	185	300	210
Urinary urea	0 6%	2.5%	1 6%
Ammonia nitrogen to urea nitrogen ratio	1 to 50	1 to 11	1 to 28
Blood urea mg in 100 c cm	20	590	80 9
Non protein nitrogen mg in 100 c cm	20	700	80 8
Amino-acid nitrogen mg in 100 c cm	4 6	10 9	7 9
Uric acid mg in 100 c cm	3 0	13 3	6 1

"Normal" Control Cases

	Minimum	Maximum	Average
Age in years	9	65	38
Systolic blood pressure	88	142	115
Urinary urea	1 6%	2 5%	2 0%
Ammonia nitrogen to urea nitrogen ratio	1 to 88	1 to 32	1 to 61
Blood urea mg in 100 c cm	26	45	34
Non protein nitrogen mg in 100 c cm	26	44	34
Amino-acid nitrogen mg in 100 c cm	4 8	6 9	5 7
Uric acid mg in 100 c cm	0 9	3 0	2 2

Urea in the urine was estimated by the alkaline sodium hypobromite method, and the ammonia nitrogen content by titration with formalin and standard alkali

In 68 per cent of cases of high blood pressure the urinary urea was less than 2 per cent , in all cases the amount of ammonia was high, so that the ratio of ammonia nitrogen to urea nitrogen was in all but four instances (16 per cent) increased to approximately 1 to 20 Since a condition of acidosis was eliminated by simultaneous determination of the alkali reserve of the patient the conclusion must be drawn that the absolute and relative increase in urinary ammonia is due to an hepatic lesion All the control cases gave normal ammonia nitrogen to urea nitrogen values

The detoxicating functions of the liver were tested by two independent means (1) an estimation of urinary indican by oxidation to indigo with Obermayer's reagent, and (2) the detection of glycuronic acid in the urine by Tollen's naphthoresorcinol test after the ingestion of 10 grains of acetyl-salicylic acid The results did not show that there was any impairment of detoxicating function of the liver as indicated by the glycuronic acid test, since only three of the series gave a definitely negative result Of these three, one was a case of diabetes mellitus with high blood pressure in an elderly patient, such diabetes being frequently of hepatic as well as of pancreatic origin, hence it is not surprising that other liver functions were also found to be inefficient In this case also there was evidence of inefficient protein metabolism, as indicated by a high ammonia nitrogen to urea nitrogen ratio (1 to 19) Two other patients were aged 70 and 80 years respectively, at this age it is not unreasonable to suppose that hepatic functions are deficient, apart from any specific disease

An excess of indican was found in 72 per cent of the cases, it is evident that this must be due either to an excessive production or to a loss of hepatic oxidative power Although indican in itself is not toxic, its presence in excess in these cases is of significance because of its association with the high amino-acid content observed in 17 out of 25 of these cases There was no history of constipation or of intestinal disturbance in any of these patients, so that a long-standing intestinal toxaemia to account for an excess of indican is improbable

Blood urea was determined by means of alkaline sodium hypobromite controlled by the soya bean method, in all cases the results did not differ by more than 2 per cent Non-protein nitrogen was estimated by the micro-Kjeldahl method, and blood amino-acids[2] and blood purins[3] by the method of Folin Blood urea values were in all cases increased beyond the normal of 25 to 40 mg per 100 c cm , results as high as 590 mg per 100 c cm being obtained The figures representing non-protein nitrogen, although raised, were not increased to such an extent as was the blood urea, so that figures less than the blood urea values were frequently obtained

An increased amount of amino-acid nitrogen was found in 68 per cent of this series of cases, figures varying from 5 to 10 9 mg per 100 c cm , instead of the normal 4 to 6 mg per 100 c cm , being obtained, this is in the main associated with a normal or relatively low blood urea content It was also noticeable in those cases in which the blood urea was raised that the amino-acid nitrogen was more or less normal This may be due to the fact that when there is serious impairment of renal function, as shown by an abnormally high blood urea, *there is* at the same time a certain amount of inorganic salt retention, with consequent hydraemia and dilution of blood constituents The relatively low values of amino-acid found in these cases, in conjunction with a high blood urea, are therefore probably more apparent than real It is of interest to note that these findings are at variance with those of Greene, Sandiford, and Ross,[4] who observed no increase in blood amino-acids in a series of 20 cases of hypertension and arterio-sclerosis in which the blood urea was normal

One is left, therefore, to conclude that the increase in the amino-acid content of the blood is due either to an inability of the liver to deaminize these compounds, or to an impairment of renal function interfering with their excretion Since in most cases of both acute and chronic renal disease there is no marked retention of amino-acids, it is probable that the increase observed in this series of cases (in which renal involvement is not particularly evident) is due to some form of liver degeneration The suggestion that liver degeneration is responsible for the increase in amino-acids is supported by the fact that these bodies are very markedly increased in acute yellow atrophy of the liver[4]

That an increase of amino-acids does in point of fact cause a rise in blood pressure is shown by the experiments of Major Stevenson,[5] who demonstrated that injections of guanidine and methylguanidine (both of them amino acids) produced a marked increase in blood pressure In this connexion also it is again of interest to note that Woolley and Newburgh[6] have shown that the long-continued injection of the amino acid indol causes hypertrophy of the

suprarenal medulla Since it is in this tissue that the production of adrenaline takes place it seems not unlikely that hyperadrenalism may be an associated factor in hypertension and that its existence may be reflected in the high amino-acid content This relationship is to be the subject of further investigation

Associated with the increase in amino-acids in this present series of cases, it was noted that there is also a very marked increase in the blood purins (estimated as uric acid) values varying between 4 0 and 13 3 mg per 100 c cm, instead of the normal 1 0 to 3 0 mg per 100 c cm were obtained The significance of this finding is not clear because it is known that uric acid of itself has no influence upon blood pressure in gout for example, there is an increase in blood urea acid without any accompanying increase in blood pressure

There is also to be noted the question of the markedly raised cholesterol content of the blood in hypertension recorded by various observers[6] That cholesterol in itself is not responsible for this pathological condition is at once obvious when the large number of patients suffering from hypercholesterolaemia, following upon biliary obstruction pernicious anaemia, diabetes mellitus, and pregnancy without concomitant affection of the blood pressure is taken into consideration However, it is said that repeated injections of cholesterol into experimental rabbits results in arterio-sclerosis[7]

The source of the increased cholesterol content of the blood is probably referable to an alteration in the cholesterol metabolism taking place in the liver, and it may be said therefore that the hypercholesterolaemia is primarily a liver condition The cholesterol normally excreted by the liver together with the bile pigments, bile salts, and other biliary constituents is derived partially exogenously and partially endogenously, that is to say, partly from sterols ingested as food and partly from the fatty constituents derived from the breakdown of red blood corpuscles, which is said to occur in the Kupffer cells of the liver The sterols are converted by the liver, partly into cholesterol and partly into bile salts[10] and it may well be that owing to the action of some toxic body upon the liver cells the normal course of metabolism is modified in favour of a production of cholesterol at the expense of bile salts Such an altered course of metabolism is known to occur and, indeed is held to be a factor in the causation of gall-stones[11] Hypercholesterolaemia is therefore probably an associated factor in, rather than a cause of high blood pressure But this also is to be the subject of further investigation

That some toxic factor is concerned is strongly suggested by the work of Cheorghian[12] who found that the injection of blood from patients with high blood pressure caused a rise in blood pressure in experimental animals It seems probable that the toxic factor is a normal product of metabolism, since it has been observed by O'Conor[13] that a high blood pressure resultant upon urinary obstruction in cases of enlarged prostate yields to suprapubic drainage Retention of this specific toxic body in renal disease therefore satisfactorily explains hyperpiesis in this condition It is to be inferred that the toxin is present only in small amount from the fact that there is no very marked difference between the blood urea and blood non-protein nitrogen figures, indeed, the non-protein nitrogen values as already pointed out, are remarkably low The series of blood urea determinations in cases other than nephritis suggested that there is some slight impairment of renal function, but not enough in itself to lead to such a degree of retention of this toxic factor as to cause an increase in blood pressure such as may reasonably be supposed to occur with gross damage to the kidney

This toxic body may conceivably be present in excess as a result of overproduction This possibility is suggested by the work of Nuzum, Seegal Carland and O'borne[14] who showed that the blood pressure of a rabbit can be raised and nodular sclerosis produced by feeding on a high protein diet for two years

The conclusion to be drawn tentatively, therefore from this present investigation is that hypertension is due to the presence in excess of a specific amino-acid This excess may be due to retention resulting from renal disease to overproduction, or more probably to some impairment of hepatic function whereby this body is not efficiently destroyed

Finally I wish to record my thanks to the trustees of the John Burford Carlill Endowment for a grant which has enabled me to carry out this work to Dr J A Braxton Hicks director of the John Burford Carlill Laboratories and to Dr F D M Hocking assistant pathologist to Westminster Hospital for their helpful advice to Sir James Purves-Stewart Dr de Souza and Dr Hildred Carlill for permission to make use of cases in their wards at Westminster Hospital

PREVENTION OF TUBERCULOSIS BY MEANS OF TUBERCULIN

BY

ROBERT CARSWELL, M A, M B, Ch B

There is general agreement that the subcutaneous tuberculin test is a *reliable test of tuberculous infection* Can anyone afford to ignore the warning furnished by such an indication, with knowledge of all the numerous minor manifestations and risks of latent tuberculosis, and of such incidents as the occurrence of tuberculous meningitis, for example in apparently healthy children? Will any thoughtful and informed individual to-day rest completely satisfied with anything short of guaranteed absence of infection in this disease? Were infection not merely frequent and inevitable, as it appears to be, but irremediable, as seems to be generally assumed, less might be said, and it is probable that a feeling of inevitability is the explanation of the calmness with which wholesale tuberculous infection is regarded, or disregarded, both by the medical profession and by the community at large

"We have all got it" they say, quite pleasantly But such was not Koch's view, and such is not the view of those who have proved for themselves or who accept the truth of his assertion that his specific method of diagnosis is almost uniformly reliable, and that, in addition incipient tubercle is can be cured with certainty Even if his specific methods of treatment be regarded as merely ancillary to the ordinary hygienic methods of cure, the contention that *nothing short of* complete eradication is a satisfactory standard would still hold force But some of us regard specific immunization not as ancillary merely, but as a prime factor in curative and preventive treatment, though experience is required to settle the important question of exactly how far we can depend upon its help alone

The above general argument was more or less embodied in a short paper, with three illustrative cases, published by me in the *Journal* four years ago (October 16th 1926 p 682), but since then it has become more clearly envisaged, and the following example was entered upon largely from the theoretical point of view that in the matter of tuberculosis nothing will be completely satisfactory in the medical history of children but definite ascertained freedom from infection indicated by a negative tuberculin test as is the common practice in veterinary work

The two girls A and B who are the subjects of the following report were at the time this record opens 13 and 14 years

of age respectively and in good, ordinary health On being submitted to the tuberculin test, however, the following results were obtained

B was negative to all five test injections (Chart II), and the Koch phenomenon was absent also In A, however (Chart I), the first (reduced) test dose produced a negligible effect, but the second injection, two days later, with twice the amount (0 0007 c cm), produced a distinct, though atypical, reaction,

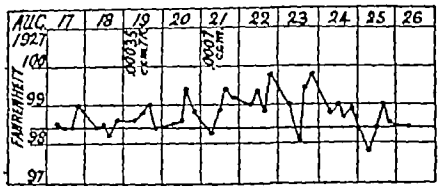

CHART I (A)

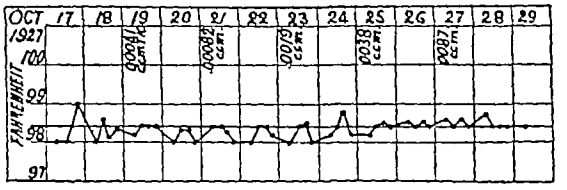

CHART II (B)

and both injection sites showed marked areas of inflammation This result in the case of A might not by itself have been accepted as conclusive, but upon proceeding with a series of immunizing injections numerous slight typical reactions were soon forthcoming, including one or two of a more pronounced character, illustrated in Chart III

There was therefore no doubt as to the positive reactivity of this case

There was no evidence of focal reaction anywhere, a few minute cervical glands, such as are common in children, may have harboured a trace of infection, or this may have existed in bronchial, mediastinal, or mesenteric glands, but there was no evidence Nor was there anything suggestive in the medical history She had had a severe attack of broncho pneumonia when a few weeks old There was a liability to colds in the head, which often went down into the chest, but were apparently of an ordinary type, a tendency to get hot and perspire at night, and a tendency to occasional slight marginal blepharitis

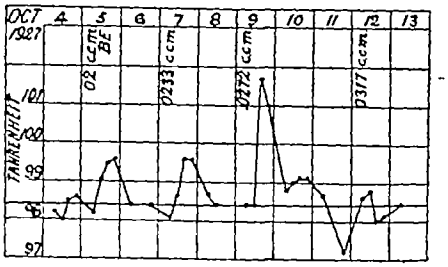

CHART III (A)

Otherwise her general health was very good, though she was considered not quite so hardy as her sister Subsequent *x* ray examination agreed with the stethoscopic findings in being negative

I proceeded at once with an effort to exterminate the infection Following Koch, who still remains the most illuminating authority on method in the employment of his preparations, a course of immunization by bacillary emulsion was carried out Beginning with a dose of 0 0005 c cm B E , and rapidly increasing during the first week, a steady progression of inoculations was carried out at intervals of two, three, or five days, with a proportionate increase of dose of, at first, one fifth, then one sixth, ending in the course of three months with 0 5 c cm. B E (2½ mg bacillary substance) Throughout the course there were frequent mild reactions which, though distinct, caused little or no subjective disturbance On two occasions the temperature rose, following an injection, to 101 7° and 103 2° respectively, but even on those occasions the disturbance did not amount to more than that of a moderate and temporary febrile attack This procedure had as its objective attainment of a progressive immunity to B E , and on reaching the dose of 0 5 c cm it was considered that the child's endurance had been sufficiently tested, and it was decided to leave an interval and note the result The general effect of this course of treatment was actually beneficial, apart from the temporary disturbance following each injection, though what was being aimed at was not so much the immediate establishment of an obvious high standard of health as extinction of infection, to be gauged by a future test

After an interval of six and a half months the test was repeated in both cases, with the results charted below

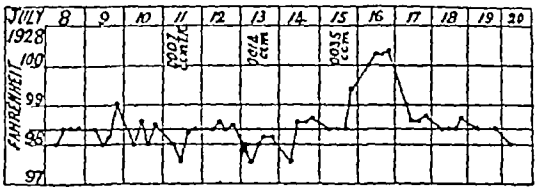

CHART IV (A)

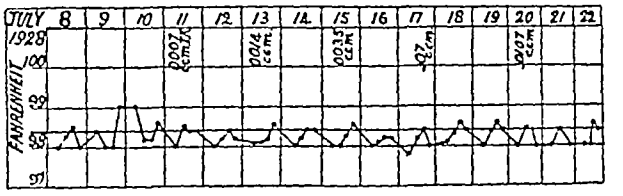

CHART V (B)

The previous non reactor B was again negative (Chart V) The previous reactor A tolerated the former reacting dose of 0 0007 c cm , and also a dose of twice this amount, with only a trace of temperature disturbance and no clinical symptoms, but reacted typically to the third test dose of 0 0035 c cm (Chart IV) On the whole she exhibited some diminution of reactivity, and seemed to be maintaining a more settled type of temperature The injection site reaction was again decidedly positive, contrasting markedly with that of the negative case Focal reaction was not observed

A second series of injections was begun five weeks later with a dose of 0 000005 c cm , and was carried out rapidly The dose was doubled with seven out of the first ten injections, the proportionate increase being then gradually reduced in the course of the next ten days to one and one sixth, which rate of increase—one and one sixth of each preceding dose—was consistently maintained throughout the remainder of the series, with the exception of the final injection of 1 c cm B E

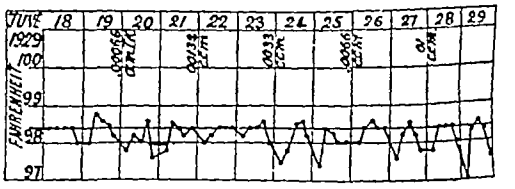

CHART VI (A)

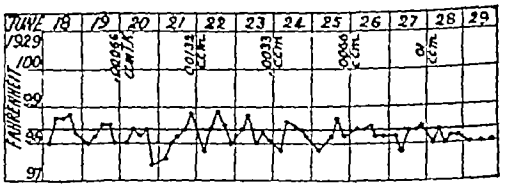

CHART VII (B)

(5 mg solid substance), which was one and one seventh During the first forty nine days forty two injections were given The interval between the next six doses was two days, and between the last three doses, three days The total number of injections was fifty, and the time occupied sixty six days The inoculations were very well borne there was less temperature disturbance than during the previous series, and little or no inconvenience was experienced The general condition was well maintained throughout, and the weight at the end was slightly more than at the beginning

The next tuberculin test, carried out seven and a half months later, was interesting, inasmuch as, in the case of A, contrary to expectation, it turned out to be completely negative The record, together with that of the control case B, also negative as before, is shown above (Charts VI and VII)

With this satisfactory evidence in hand nothing further was done in the way of treatment, there had been no particular

alteration of the general mode of life throughout According to Koch, we were now entitled to assume that no fresh or progressive tuberculosis was present which required specific treatment

After an interval of just over seven months the tests were again repeated, and were again both completely negative

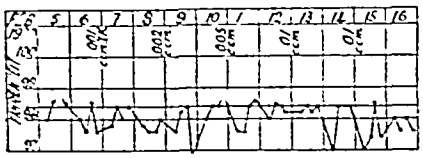

CHART VIII (A)

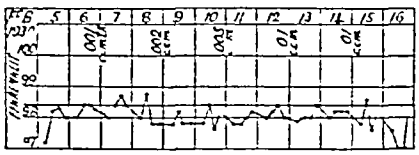

CHART IX (B)

There was no restriction of activity during any of the reported tests, so that the influence of exercise upon these temperature records is not excluded.

A few words may be added concerning the findings at the sites of injection There was in general distinct evidence in the reactor during the reactive period, of the incidence of the Koch phenomenon—increased inflammatory reaction at the injection site—in striking contrast with the entirely negative, or quite trifling, effect in the case of B, but it is of interest to note that even after A's temperature test record had become entirely negative there was still a distinctly greater degree of local sensitiveness in her case than in the case of B This is believed to be due to a corresponding inherited difference in the quality of the tissues, A's skin being soft and fair and easily reddened by the sun, while B's skin is firmer, darker, and less sensitive It should be noted, however, that there was a *relative* diminution in sensitiveness in the case of the reactor, as, during the phase of positive general reactivity, her injection site reactivity was also distinctly greater than it became subsequently, at the time of the two negative general tests

These results are a source of legitimate satisfaction, as both individuals can now be placed in the tuberculin-tested negative group, and guaranteed, so far, free from tuberculosis The details of the testing process have been completely mastered by the patients themselves, and entail no inconvenience and no trouble beyond the taking of the temperature record It is purposed to repeat this test annually in future, at all events for a time

Can this be taken as an example? I believe it can to some extent, for it is the actual accomplishment of a result which was deliberately aimed at beforehand and which, on theoretical grounds, has much to support it The subcutaneous tuberculin reaction is generally accepted as definite proof of infection, and there has now accumulated a large body of evidence in support of the curative efficacy of tuberculin treatment If this be accepted the conclusion is clear We have here a method of elimination worthy of close attention and elaboration In a search for other preparations and other procedures have we not strayed from the path clearly pointed out by Koch so many years ago?

FORTY CASES OF HYDATID DISEASE

BY

CYRIL H CUFF, M B, B S, F R C S Ed,

SURGICAL SPECIALIST CYPRUS

HYDATID disease in Europe is sufficiently uncommon to warrant occasional reports on series of cases, with special reference to treatment and results The etiology of the disease is too well known to require special comment here Suffice it to say that in primitive agricultural countries where sheep and dogs abound and proper slaughter-houses are rare the echinococcus finds its ideal home

Propagation is effected either by direct contact with dogs or by the use of contaminated feeding utensils There appear to be no special symptoms characteristic of hydatid disease, those produced originating from the presence of a tumour causing pressure upon, or destruction of, adjacent structures These secondary symptoms vary considerably, depending upon the site of the cyst and its size, typical examples are jaundice, pruritus, ascites haemoptysis, etc

Rupture is uncommon, though one of my patients (No 35) was admitted as suffering from a perforated gastric ulcer of which he showed many classical signs Laparotomy, however, revealed rupture of a hydatid cyst close to the portal fissure Suppuration occurs occasionally, and may give rise to all the symptoms of an acute cholecystitis (No 40) Gall stones and chronic cholecystitis have been noted in two patients (Nos 16 and 20), both of whom were subjected to cholecystectomy

From Table I it will be seen that in this series the incidence of the disease among males and females is equal, and that the majority of cases have been of the liver The exact figures are cysts of the liver 31, other sites 9 As ascertained up to June 30th 1930 the results of treatment were as follows cured 29 relieved 6 died 5 Considering the poor physique of many of the patients, a number of whom were also suffering from chronic malaria, these results may be regarded as quite satisfactory The period covered by the series is from September 1926 to April, 1930 the cases in Table I which are in chronological order show a remarkable sequence of male and female patients

TABLE I.

No	Sex and Age	Site	Treatment	Result	No	Sex and Age	Site	Treatment	Result

Notes.—In Case No 5 an operation was recently performed for [illegible] cyst. In 16 and 18 were associated with [illegible] Nos 36 ruptured into peritoneal cavity and No. 40 had acute [illegible] C=cured B=relieved D=died.

OPERATIVE TREATMENT

Cysts of the Liver

The methods adopted in the case of liver cysts are three in number (1) drainage, (2) drainage with partial obliteration of the cavity (3) complete removal In the present series 18 cases were treated by drainage, 3 by partial obliteration, and 20 by complete removal

Drainage consists in exposure of the cyst, evacuation of the contents, removal of the endocyst, and fixation of the tube Where possible in these cases I usually suture the parietal peritoneum around the proposed site of drainage as a protection against leakage, but in large or multiple cysts this is not feasible Preliminary sterilization of the contents by injection of formalin is practised in all methods The duration of post-operative drainage varies with the size and nature of the cyst The wound is generally healed in three weeks, in some cases, however, discharge may continue for many weeks, and is often bile-stained, occasionally a troublesome sinus persists, which may require radical treatment

This is a simple and satisfactory method of dealing with the majority of cysts

Drainage with Partial Obliteration —The essential difference between this method and that of simple drainage is that an attempt is made to diminish the size of the ectocyst by approximating its walls In the three cases thus treated this has been effected by means of superimposed layers of continuous catgut sutures after excision of as much of the membrane as possible The cavity has not been completely closed, a small rubber drain being left in its upper portion for three days For large cysts with soft walls, and where the endocyst has been removed *in toto*, I consider that this is a sound method of treatment

Complete Removal (Exsection) —Cysts of moderate size, especially those near the free border of the liver, may be completely removed by a wedge-shaped exsection which includes a portion of the liver substance Haemorrhage, as a rule, is not serious, and can be controlled by finger pressure, clamps, or gauze The resulting wound in the liver is closed by a series of deep mattress sutures and by a superficial running suture The results of this operation are extremely satisfactory in suitable cases No drainage is required and patients make a rapid and uneventful recovery

Note —The adventitia should be separated from the liver as far as possible by blunt dissection or gauze, thus reducing the actual incision to the smallest possible dimensions

TABLE II

	Cured	Relieved	Died	Total
Drainage	10	4	4	18
Obliteration	2	1	—	3
Exsection	10	—	—	10
Total	22	5	4	31

From a study of the above table the results of treatment may be easily seen All cases treated are included Cases are reported as cured where the wound is soundly healed and where there is no return of symptoms, and relieved where, although the general condition of the patient is good, a sinus persists These latter have all been large calcareous cysts with suppuration of contents Of the four deaths, three occurred some months after operation among patients with enormous cysts involving practically the whole liver, and were due to hepatic insufficiency The fourth died of post-operative shock

Extrahepatic Cyst

These, which numbered 9, were situated as follows rectus femoris 1, ischio-rectal fossa 1, lung 3, omentum 3, uterus 1 The cysts in the rectus and ischio-rectal fossa presented the appearance of chronic abscesses, and were recognized only at operation, which consisted of evacuation, swabbing with formalin (2 per cent), and packing with bipp

The uterine case was sent in with severe haemorrhage This patient was aged 55 and a nullipara On examination, the uterus was found to be enlarged and soft, the os was patulous and admitted two fingers The vagina contained several small cysts and others were expressed from the uterus The condition of the patient was very poor and precluded hysterectomy The uterus was evacuated with a flushing curette, and a number of small hydatids and a large piece of endocyst removed Haemorrhage was free, and the cavity was packed with flavine gauze The patient improved and left hospital, having refused further treatment She died one month later from what was stated to be a severe haemorrhage

Of the three lung cases, one patient refused operation the other two were treated by resection of ribs, suture of pleura, drainage, and removal of endocyst The operations were done under local anaesthesia, and the wounds healed rapidly Two of the omental cysts were lying in the pelvis and bound down by adhesions The third was situated in the epigastrium and was freely movable They were excised intact together with a portion of omentum

TABLE III

Site	Cured	Unchanged	Died	Total
Rectus femoris	1	—	—	1
Ischio-rectal fossa	1	—	—	1
Uterus	—	—	1	1
Omentum	3	—	—	3
Lung	2	1	—	3
Total	7	1	1	9

Diagnosis

In a hydatid country the possibility of a cyst is always in the surgeon's mind, and in the case of the liver there is seldom difficulty in making a correct diagnosis In other sites the difficulties are greater and the symptoms and signs less definite Diagnosis is occasionally rendered easy by the presence of portions of hydatid material in the faeces, urine, or sputum X-ray examinations and laboratory tests are of considerable help in doubtful cases The three lung cases referred to were all well demonstrated by radiography, all gave a positive Weinberg reaction (complement fixation), two a positive cutaneous test (Casson) Eosinophilia occurs in about 50 per cent of cases, but the blood film is not of great value, especially when chronic malaria is a concomitant condition

I have to thank Dr M Gosden bacteriologist for undertaking the laboratory investigations, and Dr E J Blackaby, district medical officer, for permission to include Case No 18

FOREIGN BODIES IN THE UPPER CONJUNCTIVAL FORNIX

BY

THOMAS COLLEY, F R C S Ed,

SURGEON TO THE WEYMOUTH AND DORSET COUNTY ROYAL EYE INFIRMARY

The following two cases were recalled to my mind by a report of a somewhat similar case published in the March number of the *British Journal of Ophthalmology* by Mr Sawhney These cases are of particular interest, since it is quite possible for the presence of such foreign bodies to be overlooked, when abscess formation would undoubtedly follow Once a case of this type has been recognized there should be no difficulty in making a diagnosis or suspecting the condition in subsequent cases

First Case —In November, 1929, a man attended my out patients' clinic with a muco-purulent discharge from the right eye, he stated that while threshing a week previously something had entered this eye The appearance was typical of muco purulent conjunctivitis, the lashes being stuck together with inspissated discharge, the upper lid, however, was somewhat more thickened than one would have expected On separating the lids the bulbar conjunctiva and that of the lower fornix were relatively clear except for slight injection, eversion of the upper lid showed the conjunctiva to be somewhat injected, but not to the extent that the external appearance suggested The discharge appeared to come from the inner end of the upper fornix, but even when this area was prolapsed by pressure on the globe with the upper lid everted, no foreign body could be detected This part of the conjunctiva was intensely injected and somewhat thickened The cornea and the eye itself were normal throughout

Local treatment consisting of frequent lavage with boracic lotion drops of colloidal silver and yellow ointment was prescribed and considerable improvement ensued the oedema of the upper lid gradually disappeared on the outer side but persisted over the inner end The conjunctiva cleared rapidly but considerable discharge was present which still came from the inner end of the upper fornix Further examination of this region now showed the presence of a small granulation

With the conjunctiva anæsthetized by cocaine and the upper lid doubly everted this granulation was gently scraped with a sharp spoon and a yellowish white point was exposed This was seized with a pair of forceps and a piece of macerated straw almost an inch in length was withdrawn from the orbital tissue The condition cleared rapidly in the next three days and a week afterwards the patient was discharged

Second Case—In July 1930 a man presented himself at my hospital clinic for treatment giving a history that while threshing a week previously a piece of barley straw had blown into his right eye The upper lid was inflamed and considerably thickened the man being unable to raise it The site of inflammation appeared to be in the region of the lacrymal gland where a definite welling was present there was a light muco-purulent discharge but no fluctuation of the swelling was obtained by palpation On raising the lid the appearance of the globe was normal there was however slight limitation of movement upwards and outwards The cornea was clear and the conjunctiva mildly injected The lid was so thickened by oedema—especially the outer part—that it was impossible to evert it

A hand retractor was employed and the lid was raised when the discharge was found to come from the outer part of the upper fornix where the conjunctiva was raised in folds by oedema This region was washed out and a bead of pus was noticed coming from between two folds which when separated revealed the end of a piece of barley straw This was removed with forceps it appeared to have been embedded in the palpebral portion of the lacrymal gland The condition resolved satisfactorily in forty-eight hours and the man was discharged in six days

It is quite common especially in rural areas, to see cases where pieces of straw or like material have been retained in the upper fornix for considerable periods The upper fornix is a cul-de-sac, which is formed by the reflection of the conjunctiva from the upper lid on to the globe The sensitiveness of the conjunctiva is relatively low and since the anatomical structure of this area is such that foreign bodies are held well away from the sensitive cornea their presence is often undetected by patients until a local reaction has been set up

Foreign bodies in this position produce a clinical picture which is fairly typical Pain is usually absent, and the discharge at first watery, quickly becomes muco-purulent The upper lid becomes oedematous and the superior palpebral fold puffy The lashes stick together with discharge, but when the lids are separated the conjunctiva appears fairly healthy The upper fornix however, is the site of an intense reaction the intensity being dependent on the length of time during which the foreign body has been retained In some cases ulceration may take place and the foreign body be found embedded in granulation tissue It is also feasible to think that such foreign substances as straw, which are relatively sharp, and which at first lie horizontally along the fornix, may later cause ulceration, and the action of the lids may actually drive them into the tissues of the orbit

In the first case recorded I believe that the straw actually penetrated the conjunctiva of the upper fornix on entry since there was no ulceration and only one *small* granulation locally at the point of entry but in the second case, where there was much local inflammation and reaction the straw might have been thrust into the orbital tissues through a softened and ulcerated conjunctiva In all cases where a muco-purulent discharge is present on one side only, and where lacrymal obstruction and dacryocystitis are absent, the necessity of complete eversion of the upper lid and an exploration of the upper fornix cannot be overemphasized

Had these two cases been seen soon after the entry of the foreign bodies it is more than possible that their presence would have been detected either in the fornix itself or penetrating through a conjunctiva which would at that time have been practically normal Advice was not sought, however until some seven days after the entry, when the clinical picture was much more like that of a lid abscess.

Memoranda

MEDICAL SURGICAL, OBSTETRICAL

NICOTINE POISONING BY ABSORPTION THROUGH THE SKIN

The causal circumstances in the two cases here reported appear to be unusual

A. B aged 19 an undergardener was seen at 10.30 a.m. on December 21st 1929 suffering from prostration abdominal pain, *and violent sporadic vomiting sickness having come on about* 6 o'clock on the previous evening continuing at short intervals all night F. K. aged 34 head gardener was seen in a similar condition at 3.30 p.m. on December 21st vomiting in his case having started at 9 p.m. on the 20th continuing at intervals of about half an hour The vomitus appeared to be chiefly bile In both cases the bowels were confined temperature subnormal pulse thin and accelerated (slightly irregular in the case of A. B.) tongue dry and yellow-coated skin on the extremities pale and cold There was marked muscular relaxation in the lower extremities The slightest attempt at movement appeared to induce further retching and vomiting A. B had cycled home a distance of two miles at 5 p.m. and felt ill immediately on taking a cup of tea F. K. who lived at the gardens had tea at 6 p.m. and first felt sick two and a half hours later

Both men were of robust physique and could offer no explanation of the trouble Questioning elicited the statement that from 2 p.m. till 4.30 p.m. they had been applying a winter wash insecticide to trees in a peach house The solution in a strength of one part to sixteen of water was well worked into trunks and branches using a motor-car spoke-brush an instrument calculated to splash liberally the hands forearms and face. To reach inaccessible parts and small twigs against the wall the brush was dispensed with and the bare fingers used After work they found it difficult to remove the brown stains from the skin. F. K. had had previous experience of this wash and seemed to remember that it had made him feel sick before He usually smoked while at work but had not done so on this occasion.

A tin produced was labelled XL All Liquid Insecticide. Nicotine 3.7 per cent Caution When spraying or dipping for a length of time rubber gloves should be worn Though printed in large type neither caution nor other particulars had been read.

Stimulants were given heat applied to the extremities the bowels opened with calomel and a dessert-spoonful of kavlene administered every fifteen minutes for three hours by which time in each case vomiting ceased F. K. was well in two days A. B who had done much less brush work and more finger-dipping had some abdominal discomfort for a week and was shaky on his legs for ten days

A wide literature centres round nicotine poisoning in relation to tobacco smoking the volatile alkaloid, existing as organic salts being dissociated by heat Toxic effects from smoking, however, are not referable to nicotine alone, as the volatile chemical compounds pyridine picoline, and lutidine (all having a similar physiological action to nicotine) are likewise dissociated while in addition carbon monoxide in high proportion may be inhaled Nicotine and the still more powerful oil nicotianin are both soluble in water and alcohol and are readily absorbed through the skin.

The poison produces a very complex mixture of effects—successive stimulation and paralysis of a variety of central and peripheral structures among these stimulation and paralysis of the receptive mechanism of striped muscle[1] When anæsthetics were rudimentary, relaxing rather than anæsthetizing, tobacco was a favourite among analgesics administered per rectum In recent times a case is recorded of a convict who secreted an ounce of cut Cavendish tobacco in his rectum and successfully conveyed it past the searchers but failing to recover it was four hours later in a state of collapse, with nausea, vomiting and paralysis of both legs He recovered Toxic effects following the external application of the leaf are on record,[2] chopped tobacco leaves being applied under a bandage to a varicose vein which had been accidentally wounded The patient became prostrated and pulseless, with nausea and vomiting but recovered after several days

The nicotine content in the insecticide above mentioned is stated to be 3.7 per cent, so far as can be ascertained, the proportion in proprietary sprays and washes varies from 2 to 38 per cent 'XL All" Fumigator, used for agricultural and horticultural purposes has a nicotine

[2] *British Medical Journal* 1871, vol. i. p. 154.
[3] *Lancet* 1872, vol. i. p. 284.

content of 37·3 per cent, a fatal case of poisoning (by the mouth) having been reported with this solution. I have been unable to find references to other cases of poisoning by nicotine-containing insecticides where the skin is the channel of absorption, but it is evident that such solutions, even where the nicotine content is relatively low, have considerable dangers when the cautions as to their use are disregarded.

I acknowledge with thanks assistance received from Messrs Martindale, of New Cavendish Street, in consulting references.

NORMAL PUERPERIUM FOLLOWING LABOUR IN A LATRINE

I would wish to record the facts of the following case not only because they are so extraordinary but they have added interest in showing that the grossest neglect and ignorance of pregnancy and parturition do not necessarily lead to grave disaster to the mother.

In December 1929, I was called late at night to see an unmarried primipara from a neighbouring district. This was a girl aged 20, a domestic servant who had been ill for a week with a throat and had been under the care of her panel doctor. As she could not be nursed at her place of service she was taken to the home of her relatives. She had a slight tonsillitis and a temperature of 101° F. for a day but no rash or signs of scarlet fever, and it was feared that she also was developing this infection. She had a slight tonsillitis and a temperature of 101° F. for a day but no rash or signs of scarlet fever, and it was feared that she also was developing this infection. She had rather a profuse loss of blood, which was thought to be menstrual. Palpation of the abdomen revealed a small lump which might have been an enlarged uterus and she was questioned several times as to whether she was or had been pregnant. This she denied. After eight days in bed she recovered sufficiently to be able to go out, and called weekly at the surgery for her certificate for sickness benefit.

Early in January the body of a dead full-time child was found in a box in the backyard of her former place of service, and she was arrested and charged with infanticide. After her trial, at which she was dealt with very leniently, she came to see me, and told the following story.

She knew she was pregnant but made no preparations whatever for the birth of the child. She even stated that she believed that the child emerged from the front of the abdomen near the navel. One night in November she had a pain in the back but went to bed and slept well until about 4 a.m., when she felt the need of going to the closet which was outside in the backyard. She sat on the closet seat and felt something drop from her, she fainted and did not come to until about an hour later, when she discovered that her baby had been born and was lying in the pail. She held it to her cheek and as it felt cold she concluded it was dead. She then searched in the dark among some empty boxes and found a piece of tin by which she cut the cord. She placed the dead child in a box and went into the house, where she carried on with her domestic duties, lighting the fire, preparing breakfast, and cleaning the front door steps. At break-fast she had some tea and then felt the desire to go to the closet again. She went there and felt something drop into the pail. She hid the washing during the day and as she did not feel well she went at night to see her panel doctor who sent her to bed and attended her until she left the house a week later. I did not see her again until she came under my care.

Here then, is a young primipara actually in contact with a scarlet fever case a few days before the birth of her child which occurred under the most appalling circumstances without help from anyone. The birth took place at 4 a.m. and the placenta was returned until 9 a.m., when it came away naturally, yet, in spite of all this she did not develop puerperal fever or even pyrexia, for the temperature of 101° F. lasted less than twenty-four hours. In her case the child was sacrificed to the circumstances of its birth, but even here the child might have survived had the mother been in the recumbent posture and so evaded the syncope which naturally followed the shock of birth in the sitting posture on the closet seat.

When this case is contrasted with others—for example, those I recorded in the *British Medical Journal* (October 4th, 1930) in which puerperal sepsis occurred in spite of every precaution—it seems difficult to avoid the conclusion that there exist varying degrees of natural immunity to streptococcal infection. How can we estimate the amount of that immunity and how can we increase it in those in whom it is deficient? These seem to me among the most important problems connected with puerperal infection.

Reviews.

BRIGHT'S DISEASE

Since the Bright centenary in 1929 there has been a considerable output in all countries of books relating to the many problems still awaiting solution in diseases of the kidneys. *Hypertension and Nephritis*,[1] by A. M. Fishberg of New York, is one of the latest to appear. This is a very complete book, its purpose, as the author states, is to depict our present knowledge of all the heterogeneous group of diseases which may be included under the term Bright's disease. In noticing a book with such wide scope we can only pick out a few points which may interest potential readers. One chapter entitled "Hypertensive Encephalopathy" invites some study to see what exactly is meant by a term not commonly employed in this country. It is found that this term has been applied by the author and Oppenheimer to describe the cerebral symptoms occasionally met with in high blood pressure, which have generally been defined as acute anæmia. Fishberg states that recent observations, especially by Volhard, show that these cerebral symptoms may occur when renal function is intact and without any changes in the blood chemistry. On these grounds, therefore, he believes that a uræmic origin is to be discounted, and that a new descriptive term is essential. The chapters of interest to many readers will be those devoted to the varieties of "nephrosis." Fishberg is evidently a whole-hearted believer in the concept of nephrosis, and the need for such a term in contradistinction to nephritis, and he traces carefully the development of the nephrosis conception since the word was first coined by Friedrich Muller. It is pointed out that the use of the word must now be narrowed so as to exclude renal disease consequent to primary degenerative diseases of the blood vessels, but otherwise "the nephroses may be defined as diseases characterized anatomically by primary degenerative lesions of the renal parenchyma" (p. 245). The conditions included as acute and chronic nephrosis having been described, the reader is then carried on to acute and chronic glomerulo-nephritis. Acute interstitial nephritis is given a short section, but chronic interstitial nephritis does not appear as such in the book at all. It will thus be seen that all the old possibilities for argument on nomenclature and classification are well stirred up by this book. The last 150 pages are given up to a discussion of all the aspects of "essential hypertension" or hyperpiesia, and admirable common sense is written on the question of how to deal with such cases. One very important remark is that in many cases it is best not to attempt to alter the blood pressure at all. This, however, is more true in women than in men. It is in a very remarkable how women may enjoy long life with high blood pressure, while in men the period of survival is, on the whole, so much shorter. References to literature and a good index are provided, and the book is well produced.

A recent addition to the Anglo-French Library of Medical and Biological Science is a translation, by Dr. M. Marcus, of Achard's book on the problems of Bright's disease.[2] French work on this subject has had an almost predominant position in the last decade, the names of Achard, Widal, and Blum occur at once to all students of renal disease. The book is divided into four parts. Part I deals with the pathological anatomy of oedema, the chemical composition of dropsical fluids, and the characters of the blood itself in dropsy. Part II is clinical, and discusses the sites and special localizations of oedema. A special section is devoted to the important but very difficult question of cerebral oedema. Part III, the most important division of the book, gives an admirable critical review of all the theories and facts relating to the pathogenesis of oedema. The well-known experimental and clinical work of Achard himself is incorporated into this section, which is a model of clear exposition. Part IV is short and deals with the

[2] *The Oedema of Bright's Disease*. By Ch. Achard. Translated by Maurice Marcus, M.B., B.S. Lond. The Anglo-French Library of Medical and Biological Science. London: Kegan Paul, Trench, Trubner and Co., Ltd. 1930. (5½ × 8, pp. x + 231. 9s. net.)

treatment of renal oedema No new methods are advocated, and it is a little odd to English readers to find no mention of Southey's tubes for the mechanical removal of excessive oedema of the lower limbs It is curious how this instrument, which many people would claim to have great advantages, when properly used over scarification, seems to have completely dropped out of knowledge on the Continent and in America There is a very complete bibliography at the end of each part of the book, and the translation into English has been very well done The book is well got up and printed, and the price is moderate

PLAIN WORDS ABOUT OLD AGE

It may reasonably be held that a review should point out to what class of reader a book will appeal—for example, to the general public or the experts, to the young or those well stricken in years—and it may therefore at once be said that Professor A S WARTHIN'S *Old Age The Major Involution, the Physiology and Pathology of the Aging Process*[3] may be unhesitatingly recommended to the general reader who is beginning to realize that he should order his life in accordance with the dictates of wisdom This well written and well illustrated book is an expansion of the Wesley M Carpenter Lecture delivered under the title of "The pathology of the aging process" on October 1st, 1928 at the New York Academy of Medicine, and presents a rational philosophy of old age in order to act as an antidote to fantastic ideas of life extension to extreme limits and of rejuvenation Senescence is a normal involutionary process due primarily to "the gradually weakening energy charge set in action by the moment of fertilization, and is dependent upon the potential fulfilment of function by the organism" When this normal involution has reached such a degree that one of the vital functions can no longer carry on, normal or biological death occurs but in a pathological experience of thirty-eight years Professor Warthin has not seen more than twenty-five necropsies in which this diagnosis of pure intrinsic senile death was justified and he regards myocardial atrophy and inadequacy as the most probable terminal lesion Further, the cause of intrinsic biological death is an inherited character in the cell, and is fixed for the given species Pathological death which is the lot of the vast majority may be either extrinsic or intrinsic extrinsic death is theoretically preventable, and against all environmental factors modern sanitary science is conducting a fight which eventually will raise the average life limit to 55 or 60 years Intrinsic pathological death is inherent in the germ plasm and is seen in inherited disease, as a mutation or as the result of a blastophthoria (toxic degeneration of the germ cells), and its prevention is a genetic problem to be solved only by a breeding-out process Examples of such diseases are arterio-sclerosis and cancer No encouragement is given to the optimistic prophecies that man's age will average 125 years or more, for statistics are quoted to prove that the recent increase in the average American age is due to the saving of life in the earlier decades and indeed that there has been a loss of nearly half a year in the expectation of life in the males of Massachusetts at the age of 72 in 1920 as compared with 1880 Of the effect of Steinach's and Voronoff's operations for rejuvenation Professor Warthin's verdict is stern—namely that the so-called rejuvenation is only a re-erotization and "but a myth of ancient lineage disguised in quasi scientific garments

CANCER AND ERYSIPELAS

Most of the modern theories of the causation of cancer rest on some definite experimental fact such as the presence of a micro-organism or the action of an extract of the growth Professor LÉON BOUVERET in his essay on the Pathogeny of Cancer[4] maintains that insufficient consideration has been given to the general characteristics of cancer as a basis of inference as to its causation He has therefore studied cancer in all its relations as ascertained in the literature available to him, and from this material he has evolved a theory which, if somewhat difficult of acceptance, has at least the merit of originality

The central point of his argument is that certain well-ascertained facts indicate the existence of a close relationship between the streptococcus of erysipelas and the causal agent of cancer As every surgeon knows, an attack of erysipelas in a cancerous patient may be followed by retrogression or disappearance of the growth, Coley's treatment of sarcoma is based on this fact The precise relationship between the two conditions has apparently not received very close investigation, and is, in the author's opinion, too readily ascribed to the associated fever In point of fact the degree of fever and the retrogression do not run on parallel lines, some of the most marked cases of retrogression having occurred with merely slight degrees of fever If fever is excluded as the cause, there remains, in the author's opinion, only the infection itself to which the change can be attributed In regard to this he notes two striking facts that retrogression of the growth is not brought about by other than erysipelatous infections, and that it does not occur unless the defence against the erysipelas itself is effective, cases which end fatally showing no evidence of retrogression in the growth From these facts the author argues that the same antibody which defends against the streptococcus of erysipelas also exercises a specific action against the cancer cells It is in connexion with this identity of action that the author's theory is introduced He concludes that the cancer cell contains some element of streptococcal origin—not the streptococcus itself, but some product of it, which retains a part of its properties. He conceives that a complex microbe cell is formed in which are united the properties of the cell and of the micro-organism, and that the combination is effected by the activity of the cell itself, a cell possessing abnormal and malignant properties being the result

The theory appears to bring many of the features of the process of malignancy under a single point of view, and the author is undoubtedly right in urging that the relationship between erysipelas and cancer deserves closer investigation than it has received hitherto

A SURVEY OF TUBERCULOSIS

THE Results of Tuberculosis Research,[5] the first volume of which is published under the editorship of Professors Assmann, Beitzke Braeuning, and St Engel, was projected under the conviction that the literature of the subject had become too vast to enable any one man to undertake a complete exposition or to obtain more than a partial knowledge of the subject from his own personal reading In these circumstances the only possible course to pursue was to split up the subject placing each subdivision in the hands of those most acquainted with it It does not appear that this course has previously been adopted in the case of tuberculosis and the result is very satisfactory The book is not confined merely to the description of the recent advances made by research, it appears to aim at a complete exposition of our present knowledge Thus in the excellent preliminary article contributed by Professor Klemperer on the early diagnosis of pulmonary tuberculosis a detailed description is given of the physical signs and the proper methods of eliciting them The editors have however so far limited the subject that only matters of actual practical importance are included in the work. The present volume contains articles on the early diagnosis of pulmonary tuberculosis, the early infiltrate healing processes in pulmonary tuberculo is and its recognition by means of x rays immunization against tubercle the present position of the problem of allergy the biological basis of the chief non-specific blood reactions in tuberculosis, methods adopted in combating the disease and the demonstration of the primary focus in the lung by means of x rays It will be seen that the practical aspect has been kept in view in the subdivision of the

subject, and there can be no doubt that the work will be of value to those who are engaged either in the study or the treatment of tuberculosis A second volume, completing the work, will shortly be published

ATHLETIC EXERCISES

DR ADOLPHE ABRAHAMS is so well known as an authority on athletics that a book by him on exercise[6] is sure of a favourable reception In his preface he states that so far as he is aware no attempt has hitherto been made to consider the subject of exercise in general with the particular indications for the varying requirements of age, sex, and physical capacity He takes a broad view of the subject, and recognizes that there is a psychical as well as a physical side to the matter considered, which is not the least important He dismisses as a bugbear the fear of overstrain in young adolescents and healthy adults

In only ninety-two pages Dr Abrahams discusses under twenty-two chapter headings all sorts of exercises and their suitability for either sex and various ages, and his advice is characterized by strong good sense All these chapters are pleasant to read, and should be profitable to those who need advice as to what exercise they should take and its limitations in various cases Some of his readers may be surprised to see that he thinks that rowing gives little employment to the arms and to the chest, but most to the legs This of course applies to rowing on sliding seats in racing boats The decaying sport of rowing in fixed boats on fixed seats called into use the muscles of the back, chest, and arms to a much greater extent

RADIOGRAPHY OF SPINAL CORD LESIONS

IN an interesting monograph published as a supplement to *Acta Radiologica*, Drs M ODIN, G RUNSTROM, and A LINDBLOM describe their experiences with iodized oils in the diagnosis of lesions of the spinal cord In the course of their work with lipiodol these authors found that such large amounts of this substance were required to show up indefinite lesions of the cord that its use was sometimes followed by dangerous reactions, and they proceeded to examine other substances with a view to discovering one that could be used with safety Good results were obtained with iodized sesame oil, and with its aid they investigated a large number of cases, including cases of tumour and of trauma in which the radiological information proved to be of great value Particularly interesting was their discovery that in certain patients with symptoms of sciatica the iodized oil revealed the presence of adhesions round the lumbar cord To this condition they have given the name "adhesive arachnoiditis," and in the monograph they discuss its diagnosis and treatment In the course of their work they describe fully the procedure for injecting iodized oil into the spinal theca, and give full case records of a number of patients

NOTES ON BOOKS

DRS I I ELIASON and L KRAEFER FERGUSON and MISS ELIZABETH KELLER LEWIS the authors of *Surgical Nursing*[8] having learned from experience that nurses make fewer mistakes and work more efficiently when they understand not only what they have to do, but why have tried to give the reasons as well as the technique of each procedure they describe in their book They have skilfully blended instruction in the basic sciences with their account of the actual detail of nursing practice emphasizing however, that no amount of theoretical instruction can take the place of bedside experience in the making of an efficient nurse Throughout the book whether they are describing general nursing methods anaesthesia, or the pre and post operative care of the surgical patient, their presentation is precise and detailed especially so in the section dealing with the technique of the operating theatre The work is copiously illustrated with photographs and charts It may be recommended to the probationer, both as a textbook for examinations and as a guide to everyday work in the wards

The observations and opinions of various authors upon the relationship of malaria and nephritis have been very varied, and the discrepancies have never been satisfactorily reconciled An attempt to solve the problem is made by Dr GIGLIOLI in a small volume which has recently appeared under the title *Malarial Nephritis*[9] According to the author, the main characteristic of malaria and blackwater fever in the interior of British Guiana is "extreme chronicity intensified by continual reinfection and superinfection leading to a veritable malarial saturation" and he describes careful and extensive observations that were made to determine, on the one hand, the incidence of albuminuria and renal disease in malaria, and, on the other hand, the cause of renal affections as seen among the native population From these observations he concluded that persistent albuminuria and other signs of renal disease are directly proportional to the chronicity and intensity of malarial infections, and that, although *P vivax* infections predominate and are the commonest causes of kidney disease, albuminuria is twice as common in quartan as in tertian infections East Indian natives he found to be more prone to kidney affections than the negroes, and untreated cases than treated cases Case reports referring to twenty-six persons are given in an appendix

The second volume of the fortieth series of *International Clinics*[10] contains, among others, attractive papers on the diagnosis and treatment of yaws illustrated by some striking photographs by Captain C S Butler, commander of the United States Naval Medical School, the physiological basis for mechano therapeutics in heart disease, by Dr Edgar Friar, focal infection and elective localization, by Dr Edward C Rosenow of the Mayo Foundation, the treatment of acidosis, by Professor Victor C Levine of Omaha, cinchona alkaloids and bark in malaria by Professor W T Dawson of Galveston local anaesthesia in general surgery by Dr Leigh F Watson of Los Angeles and historical medical pageants, by Dr Frank K Boland of Georgia The sections entitled "Medical questionaries" and "Medical trends" contain as usual much instructive and pleasantly imparted information

PREPARATIONS AND APPLIANCES

GOMENOL

GOMENOL is a disinfectant that was introduced for medical use in France thirty five years ago Arends-Keller (*Neue Arzneimittel und Spezialitäten* seventh edition, p 224) states that gomenol is the ethereal oil of *Melaleuca viridiflora* Tests conducted in French laboratories have shown that it is a very powerful antiseptic with an activity similar to that of thymol, but that its toxicity is only one tenth that of carbolic acid Quotations are given from various authorities which show that the active principles in gomenol differ advantageously from those present in other essential oils in respect of their therapeutic properties This preparation has been used extensively in France for a wide variety of therapeutic purposes, and the agents for this country (Messrs Coates and Cooper, 41, Great Tower Street, E C 3) provide a list of nearly one hundred publications reporting on its therapeutic value

BIOCHOLINE

Biocholine is a synthetic choline hydrochloride, manufactured in Paris Carles and Leuret (*Bull de l'Acad de Méd* February 18th 1930) have reported favourably on its use in thirty two cases of tuberculosis The authors believed that in tuberculosis the cholesterol content of the blood was diminished and injected choline hydrochloride with a view to increasing the blood cholesterol The agents for this country are the Anglo French Drug Co, Ltd, 239A, Gray's Inn Road, W C 1

LACTO DEXTRIN PSYLLA

Lacto dextrin is a combination of the two carbohydrates lactose and dextrin in a form which is agreeable to take The advantage of the preparation is that it provides a palatable food material which will inhibit putrefaction in the large intestine by promoting the growth of *B acidophilus* and *B bifidus*

Psylla is the name for the seeds of *Plantago psyllium* The coats of these seeds contain a large quantity of mucilage and swell into a gelatinous mass in presence of water They are of therapeutic value in providing the necessary bulk and efficient lubrication for the large colon in various forms of colonic dysfunction The preparation is recommended for use in mild cases of constipation in fissure and haemorrhoids, and also in cases of colitis

Both lacto-dextrin and psylla are manufactured by the Battle Creek Food Company of Michigan, and the British agent are Messrs Coates and Cooper (41, Great Tower Street, E C 3)

ON THE TEACHING OF TUBERCULOSIS *

BY

STEPHEN J MAHER, M D ,

CHAIRMAN OF THE CONNECTICUT STATE TUBERCULOSIS COMMISSION

I am not a university professor of tuberculosis, therefore it may be asked by what right I presume to give advice on the teaching of tuberculosis to physicians and medical students My excuse for taking up time to discuss the social question is this for twenty years, as the responsible medical director of five State sanatoriums in Connecticut, I have been employing studying, and teaching tuberculosis physicians produced by the professors of tuberculosis in the universities of America, Europe, and Japan The banker or manufacturer who for twenty years had been employing accountants and stenographers from various business colleges of his own and other countries would probably have interesting and perhaps important opinions as to the weakness or strength of the different systems used by the business colleges to develop reliable bookkeepers and rapid and accurate writers of shorthand For *the same reason have I opinions of the modern teaching* of tuberculosis The question whether they are interesting or important I must leave for you to decide

The first criticism of the university professors' teaching of tuberculosis is that many of them do not teach it, they do not teach it as the live subject that it is to-day What they teach is a cold simulacrum of the modern problem, a plaster cast or death mask of the tuberculosis problem as it looked twenty to fifty years ago They exaggerate the dangers to which those who study tuberculosis are exposed they tell in damning detail the discouraging failures of many of the generals who have heretofore led the fight against tuberculosis they scorn all suggestions from their pupils or other students, and they raise doubts as to the absolute verity of the tuberculosis dogma that they and their textbooks teach

The graduates of such classes naturally face the work of their lives crippled with what an eminent English physician told me was somewhat prevalent tuberculosis philosophy in his country, 'the defeatist philosophy," the *philosophy of despair, the philosophy that possibly* makes good historians and statisticians but makes dangerous doctors and unfit tuberculosis specialists The doctor who has no hope or ambition of improving the present *treatment of disease not only does not study*, does not give his patients the chances for life that they should have, but he blocks medical traffic" and interferes with the scientific progress of his fellow physicians toward the faintly shining goals of success that always beckon forward the leaders of the profession the men whose vision and faith give them power to pierce the mists of "defeatism," timidity and laziness

In too many universities tuberculosis is taught as Latin and Greek or other dead subjects are taught The students are forced to memorize rules and to memorize unproven dogmatic statements Tuberculosis is not a dead subject, it is one of the most live problems of to-day The student to whom tuberculosis has been presented as a dead subject will take no other interest in it than to commit to memory such parts of the dry lectures to which he has been forced to listen as will enable him to pass his examination and to secure his medical degree or licence

Tuberculosis is one of the most fascinating studies that now engage the mind of men Yet of all the thousands of young doctors graduating every year from the medical schools and hospitals of the civilized world to how few of them has this fact been made clear! The young graduate who would announce to his class-mates that he intended to take up tuberculosis as his life work would be considered queer and sadly in need of a guardian by his fellows, who themselves were to be general surgeons internists, public health officers or medical missioners to Cathay Why do these other medical fields attract the young graduates so much more than this? It is true there is not much money to be found in the tuberculosis field but to the ambitious and sanguine thousands of young medical graduates the monetary outlook is seldom the dominating influence in deciding the question of their life's work They want chiefly to do work that will be interesting and of service to humanity It is for these reasons that the young graduate decides to become a general surgeon, or a general practitioner, or a public health official, or a medical missionary The work to be done in these various lines of medical endeavour has been presented to him in such manner as to capture his heart and mind His imagination glows as he pictures himself saving important lives as a great surgeon, or saving a whole people when David like, he kills a Goliath of plague with the pebble of some public health vaccine that he or his companions have discovered But tuberculosis has no appeal for him He has been told that it is a closed chapter that the tubercle bacillus always was, and always will be the tubercle bacillus, that tuberculosis will always kill human beings as it has always killed them and that the only possible way to drive tuberculosis from the earth is to kill all the tubercle bacilli on earth, and all the tuberculous *human beings and all the tuberculous birds and brutes* on earth Then, and then only, will parents know that their children can grow into manhood and womanhood without danger of infection from tuberculosis That, as my English acquaintance said, is the "defeatist" programme that is called teaching tuberculosis in so many medical school And it is on account of that "defeatist" programme that we do not get the brightest of the medical classe to come to us to enlist with us for saving mankind from the tubercle bacillus

In order to secure for our work a fair share of the brightest of the new graduates, teachers in the universities must revise their lectures and perhaps their own conception of tuberculosis Then they must make it clear that very little is yet known of the tubercle bacillus and of its devious ways of killing human beings, they must give the students and young physicians the opportunity to form opinions of their own on the many contentious phases of the tuberculosis problem They must introduce the young men and women to the progeny of the tubercle bacillus and to the various blood relations of the tubercle bacillus to the question of the prebacillary and the filterable viruses of tuberculosis to the problem of a possible relationship between tuberculosis and cancer to the problem of dissociation They must tell the truth about the contagiousness of tuberculosis, and do what they can to kill the phthisiophobia that they have unwittingly done so much to spread throughout the world they must explain enthusiastically to such students as have a special love of surgery the attractiveness of the vista that is now opening before all the men capable of doing lung surgery Concerning this last matter it will not be sufficient to have the young men become able merely to name and describe the various operation now known as lung surgery That kind of teaching will never stir into a flame any smouldering ember of tuberculosis enthusiasm The surgically bent students must not only learn to perform the various operations of pulmonary tuberculosis, but they must be convinced of the tremendous importance of lung surgery and the opportunity for fortune and renown that awaits the man especially the young man, who proves himself a leader in this uncrowded line of endeavour They must make it clear to all their students that what the world needs what it expects, and what every year seems to bring nearer to realization, is a cure or preventive of tuberculosis and furthermore that the race for this great prize is a "free-for-all" which is as likely to be won by the humblest student of tuberculosis as by the conductor of the most richly endowed laboratory or institute for research They must make it clear to their students that the invitation to become *tuberculosis specialists is not confined* to men who themselves are tuberculous or who fear that in some way the dark shadow of tuberculosis has fallen on them or on their families Heretofore such men have done most of the antituberculosis work of the world, and very good

* An address delivered at the International Congress of Tuberculosis Oslo August 1930.

work too, now, however, the work beckons to the ablest and healthiest of the young medical men of the world to come and to come immediately to the assistance of the somewhat tired regiments that up to now have borne the battle's burden

And we ourselves, do not let us pose as weepy martyrs, anxious to tell a world that we have sacrificed opportunity, and health, and gold, for a subordinate place in the anti-tuberculosis army. Even if most of our dreams of personal victories over the tubercle bacillus have failed of realization, even if we must still admit that we know but little of our enemy's plans and resources, even if not one funeral in every dozen funerals is caused by the tubercle bacillus, we ourselves have had more than ordinarily happy and useful lives. We have saved and gladdened the lives of many of our brothers and sisters, and we have received abundantly of the world's love and gratitude. We old fellows owe it to truth and to our young recruits in the anti-tuberculosis army to welcome them with smiles. Our appeal to them should be that of the big boy who goes first into the village swimming pool and who cries out to his young and hesitating mates on the bank: "Come on in! The water is fine!"

MEDICAL DEFENCE UNION

ANNUAL GENERAL MEETING

THE annual general meeting of the Medical Defence Union took place on October 2nd with the president, Sir HERBERT WATERHOUSE, occupying the chair. The report of the council and financial statement were adopted unanimously, and the retiring members of council, Dr. W. T. Lydall, Dr. Henry Robinson, and Dr. Seymour Taylor, were re-elected.

President's Address

In the course of some remarks on the year's work, Sir HERBERT WATERHOUSE said that claims against medical practitioners were increasing in frequency, and with the changing conditions of medical practice they were likely to increase still more in the future. Yet every year the Union was asked for help by practitioners who had failed to join a defence organization or had allowed their membership to lapse. Some of the cases dealt with during the past year had been of exceptional gravity, but in twelve in which proceedings had been threatened against the practitioner the matter was dropped when it was known that the Medical Defence Union would defend its member. In six other cases where it did not seem that a successful defence was possible, the solicitors to the Union had been authorized to effect a settlement on reasonable terms, and in every case that went to the courts the verdict returned was in favour of the member—a striking testimony to the skilful handling of the defence by the solicitors (Messrs. Hempsons) and by the counsel employed. Sir Herbert Waterhouse asked members to bear in mind, however, that successful defence must always depend to a large extent upon the evidence available to rebut the allegations, and therefore it was of the highest importance that members should make a point of preserving a record in all difficult or doubtful cases. In an unusual number of cases this year claims for compensation had been made on account of broken hypodermic needles, and in one such case a writ had been issued and proceedings were pending. One important case in which the claim of a member, supported by the Union, had been successful concerned the fee to be paid for examining, at the instance of the coroner, seven bodies, victims of an aeroplane disaster. The proceedings in the county court and the judgement were set out in the *British Medical Journal* of August 9th (p. 216). Sir Herbert Waterhouse added that the Union now enjoyed a very high reputation, which had been ably maintained and, he believed, enhanced by the work carried out during the past twelve months. He thanked Dr. W. S. A. Griffith, a past president, for attending to the duties of the chair while he himself was laid aside by the results of an accident, and he also thanked Dr. James Neal, the general secretary, and the solicitors (Messrs. Hempsons) for much valuable advice and help.

Annual Report for 1929

The annual report which was adopted at the meeting, bears witness to the progress of the Union by the announcement of a further acceptance of liability in connexion with indemnity insurance. In any case taken up by the council on behalf of a member the whole cost of the member's defence is paid by the Union, but in addition, an unlimited indemnity is provided against damages and taxed or agreed costs incurred by the member in connexion with the case. Since 1926 the council has had an agreement with an insurance company whereby the first charge upon the indemnity insurance is borne by the funds of the Union up to 50 per cent. of the subscription income. Now, in consequence of the steady growth of the reserve fund, the council has undertaken liability up to the total amount of the subscription income, thus enabling the Union to insure against any claims in excess of that amount for a considerably smaller premium than has been paid hitherto.

Particulars of a large number of interesting cases dealt with during the year are given in the report. Many of these were settled by the general secretary without resort to legal aid, but 92 cases had to be referred to the solicitors. Actions for libel and slander comprised only five of this total, and the solicitors state that complaints of this character show a marked decline. Actions involving claims for malpraxis, as usual represent more than half the cases referred. One rather interesting case is, briefly, as follows:

A well-known surgeon in the Midlands had a patient sent to him with symptoms of dyspepsia, with an abdominal tumour. He advised an exploratory operation, which disclosed inoperable cancer of the stomach. Gastro-enterostomy was performed, with marked improvement in the symptoms. The patient's husband, who was very pleased with the improvement, was advised that this could only be temporary. Until then he had been most grateful for what had been done, but on receiving the account his attitude changed and he complained that the operation ought never to have been performed. On the advice of the Union proceedings were instituted for the recovery of the amount, the patient putting in a defence alleging unnecessary operation and repudiating liability. After a short time the Union was approached by the patient's husband, who expressed regret for his criticism of the treatment of the case, but asked the surgeon as an act of grace to reduce the account. This, however, was not acceded to, and the amount of the debt was paid *in* full.

Only one action for alleged wrongful certification of the insane came into court, though one other was threatened. Application was made under Section 330 of the Lunacy Act for the action to be stayed, but owing to the judgement of the Court of Appeal in the Hume Spry case, in which one of the members of the court stated that it was not for them to examine the quality and character of the evidence before them, but that they were bound to accept any material presented by the plaintiff in support of the allegation that there had been lack of reasonable care, both the master and the judge refused to stay the proceedings. Thereupon the Union went to the Court of Appeal, and after a lengthy hearing the appeal was allowed and the proceedings stayed. An account of the proceedings in court will be found in the *British Medical Journal* for December 28th, 1929 (p. 1226). The solicitors state with regard to this result:

Without actually overruling the decision in the Hume Spry case they (the court) made it perfectly clear that in their opinion it was the duty of the court in cases of this sort to examine the quality and character of the evidence produced by the plaintiff in support of a plea of lack of reasonable care. This, in our opinion, is a signal triumph, as after the findings of the court in the Hume Spry case it was felt that it was almost useless to apply for a stay of proceedings under Section 330 of the Lunacy Act unless we were prepared to take the matter to the House of Lords.

A number of cases with which the Union has had to deal during the year have arisen out of national health insurance administration. In the majority of cases the Union has been successful on appeal either in reversing the decision appealed against, or, in cases of surcharge for alleged excessive prescribing, in obtaining a reduction of the proposed penalty.

The members of the Union on December 31st last numbered 15,886, and the annual income was £17,497, an increase of £435 over the previous year.

British Medical Journal.

SATURDAY OCTOBER 11TH, 1930

MENTAL DEFICIENCY

The section on mental deficiency in the Board of Control's report for the year 1929 does not make comfortable reading.[1] It is true that both as regards ascertainment and as regards each of the statutory methods by which mentally defective persons may be cared for, there is a small increase in the numbers; but the main feature of the report is once more the demonstration of the woeful neglect of local authorities to recognize their obligations in these matters or to take any adequate action with regard thereto. In spite of, or perhaps because of, the somewhat hysterical outcry in certain quarters and the exaggerated claims put forward for particular methods of dealing with the problem, neither local education authorities nor local control authorities seem to realize the real nature of mental deficiency, its serious prevalence in, and effects upon, the community, nor their own extensive powers and duties for grappling with the situation. Far too largely the problem is either ignored or minimized, or a pathetic and illogical reliance is placed upon procedures which may or may not some day be adopted, to the neglect of all those remedies which are immediately available.

As regards ascertainment, if the results of Dr. Lewis's investigations and the findings of the Wood Committee are to be accepted, there are some 314 000 mentally defective persons in England and Wales, or eight per thousand of the population. At the end of 1929 the number reported to the local authorities was 71 439, or 1·81 per 1 000 of the estimated population. It may well be that the numbers given by the Wood Committee are in excess of the facts, either because the standard of average normal intelligence was placed too high, or because the sample areas investigated were not actually typical of the whole country; but the disparity between those figures and those of present ascertainment is far too great to allow of any complacency. The striking difference between the activities or standards of the various local authorities is further shown by the fact that their returns vary from 5·82 (Cardigan) to 0·18 (Huntingdon) per thousand of the population. London discovers 2·27 per thousand. The report gives some striking cases illustrative of the harm which arises from the failure to discover and train mentally defective persons. Yet in spite of these dire results, which eventually entail greatly increased expenditure, it is evident that many local authorities deliberately neglect ascertainment because when defectives are ascertained, there is an obligation upon the authority to provide suitable supervision and training for them, or to place them in institutions or under guardianship, and this is often costly.

Hitherto however local authorities have suffered some real handicaps against full ascertainment. One of these has been that those mental defectives who were dealt with under the Poor Law did not fall within their jurisdiction. The passing of the Local Government Act, 1929, and the particular proviso (ii) of Section 30 of the Mental Deficiency Act have removed the most serious of these difficulties, and as the report points out, have for the first time made it possible to secure unity and continuity of treatment and care for the mentally defective. The result ought to be that within the next two or three years at most, local authorities should have made an accurate survey of all defectives within their area, that all such persons should be assisted and cared for *qua* their mental deficiency and not as destitute persons, and that a real advance should have been made towards the provision of colonies or institutions for the accommodation of that considerable proportion of mental defectives who can best be cared for therein. On these grounds there is, perhaps, a case for the exercise of a little further patience with local authorities. One word of warning is given by the Board of Control. The survey to discover the true incidence of mental defect can only be successfully carried out by medical men possessing special knowledge and experience of mental deficiency and familiar with the various types dealt with in institutions and colonies. In these days when the problem of unemployment is so urgent, a special effort should be made to distinguish those who are unemployed by reason of their mental condition from those who are capable of working if the opportunity offered. A further point may be touched on here. The report recognizes with appreciation the educational work done by the Central Association for Mental Welfare in its training courses, but states that "with the increase in the number of mental deficiency colonies it is becoming increasingly difficult to find superintendents with any specialized experience of mental deficiency work. It would be a gain to medical education and certainly to mental deficiency colonies if arrangements could be made for short post graduate courses at one or two colonies within easy reach of a teaching hospital."

The report contains some important and suggestive paragraphs on the marriage of defectives and on sterilization. The Board of Control is of opinion "that an Act prohibiting the marriage of defectives while under statutory care would be a preventive measure of great social utility. 'Not only would it draw public attention to the unwisdom of allowing defectives to marry, but it would place local authorities in a far stronger position by enabling them to insist on proper precautions being taken by the persons to whom defectives are licensed and by their parents and guardians.' On the question of sterilization the Board says: 'Sterilization will not solve the many problems of the prevention of mental defect; indeed, it is doubtful whether it will appreciably reduce its incidence. In any case, it would be absurd to suggest that its adoption would obviate the need for the institutional care and training of those defectives whose social inadaptability makes it impossible to leave them at large. But there are cases in which it might be advantageous.' This exactly states the conclusion arrived at by the Medical Committee of the Central Association for Mental Welfare and the position taken up by this *Journal*. The Central Association and the British Medical Association are alike urging the necessity for an early and authoritative official inquiry into the causation of mental deficiency and measures for its prevention including both segregation and sterilization. The demand for such an inquiry has for the moment been suspended at the request of the Minister of Health, but will probably be resumed almost immediately. It is to be noted that the Board of Control says: "We think that the whole question calls for careful study and investigation, but we recognize that scientific and impartial inquiry is rendered difficult by the atmosphere which sterilization

[1] Sixteenth Annual Report of the Board of Control, for the year 1929. Part I. H.M. Stationery Office. 1s. 6d. net.

excites, and by the exaggerated claims which are put forward by its advocates" Meanwhile, it is stated that the register of defectives which is kept by the Central Association for Mental Welfare and its local associations contains records, in many cases complete for two or three generations, of more than forty thousand cases Here is material for impartial medical and statistical investigation which should prove of inestimable value, awaiting only the financial provision which would make its examination possible The opportunity may provide the philanthropist

THE TREATMENT OF FRACTURED PATELLA

It seems to us well that the discussion at the recent meeting of the Association at Winnipeg on fractures of the patella should have been held in the Orthopaedic Section and have been opened by the lecturer on clinical orthopaedics and in orthopaedic pathology in Liverpool University, for this subject has scarcely been adequately considered in recent authoritative works on orthopaedic surgery in our language In the second edition of *Orthopaedic Surgery*, by Jones and Lovett, published in 1929, only thirteen lines are devoted to it The last edition of the well-known and otherwise excellent book by Royal Whitman of New York ignores it altogether, according to the index and table of contents, while Cochrane of Edinburgh and Willis C Campbell of Memphis (Tennessee) each devote about one page to the subject Indeed, the operative treatment of fractured patella is described and discussed with more detail in works on general surgery than it is in special treatises Yet, if there is an injury which should be treated on orthopaedic principles, this surely is one Orthopaedic surgeons not only aim at the correction of the actual anatomical conditions, and the displacements which have resulted from injury, but, in addition to such mechanical joinery work on the skeleton and soft parts, they profess to have ever in view the ultimate functional result, which in a given case may be excellent, notwithstanding that the anatomical result may be far from ideal An actual surgical operation, such as that of bone-suture, is of course important, from the point of view of the orthopaedic surgeon, but its importance may be no greater, or even less, than that of the post operative treatment

As Mr Watson Jones reminds us in his paper, which appears at page 592, we have still to solve the problem which troubled John Hunter, and to treat injuries of the extensor apparatus of the knee, of whatever nature, in such a manner as to restore extensor power without impairment of the normal range of flexion movement The early onset and obstinate persistence of atrophy of the quadriceps extensor in cases of arthritis or of injury to the knee-joint has been better known than treated for a very long time It is said to have been noticed and recorded by Hippocrates, or by one of the writers whose works have been attributed with more or less certainty to that great authority[1] Wasting of this and of other muscles of the thigh, and consequent weakness and imperfect control over the joint, are some of the most disabling effects of a broken knee-cap, or ruptured ligament or tendon, and they may be of greater importance than the nature or condition of the medium of union between the fragments of bone, or between bone and ligament or aponeurosis Some estimation may be made of the relative importance of the ligamentous and muscular elements of the knee-joint by observation of cases of congenital defect of the patella, in which the tendon of the quadriceps is nevertheless present In some of these, despite the lack of any sesamoid bone in the tendon, but with normally active muscles, although the ligamentous apparatus of the joint may be defective, the knee has been found to be of normal strength, mobility, and usefulness Of the two kinds of restriction of movement in the knee joint from patella injury—namely, reduced range of flexion and loss of power of complete voluntary extension—the latter is far the more serious and disabling In our ordinary daily life it is seldom necessary to bend the knee to within twenty degrees of its normal possibility, but the full normal volitional and postural extension of the joint is being continually called for in the erect position

In the treatment of this, as of other fractures, the indispensable factor for bony union is apposition of the fractured surfaces of bone, without interposition of soft parts Since Lister astonished and even scandalized the surgical world by daring to invade the knee joint in order to suture a broken knee-cap, a number of methods have been followed, and various means of holding the fragments in proper position have been employed Good results *qua* union have been obtained by most of these means, and the operative procedure described and fully illustrated in Mr Watson Jones's paper leaves nothing to be desired in this respect But surgeons bent upon securing a good functional result will agree with him that one must not be content with good union alone, and will demand a technique and choice of material which will from the first permit of movement of the joint without risk of tearing the fragments asunder This security Mr Watson Jones thinks is afforded by the use of braided silk as a suture As he points out, rapidly progressive atrophy of the extensors is only to be checked by use under the control of the patient's nervous system, and the true rôle of physiotherapeusis in these circumstances is not the production of passive or electrically stimulated movement, but education of the patient in the performance of those muscular actions which are inhibited by the injury The importance of postural tone in the physiology of the musculature of the lower extremity has, until recent years, been overlooked by some surgeons, but the need of teaching patients how to recover it is now recognized The principles of treatment applicable to simple linear fracture of the patella from indirect violence are applicable, *mutatis mutandis*, to comminuted fracture from direct injury, and to avulsion of the ligamentum patellae or of the insertion of the quadriceps, all of which injuries are included in the subject of this paper, and it will be obvious that in the case of comminuted fracture movements must be gentler and of smaller range at first than in a case of linear fracture, which can be so securely sutured as to be able to withstand quite vigorous exercise

Anatomy and physiology have been justly called handmaids to surgery, but some of the debt due from the latter to the former has been repaid by what Lord Moynihan has called the "pathology of the living" Until arthroplasty of the knee was made a successful procedure by Murphy and his successors, anatomists and physiologists hardly realized what an important part in the mechanism of a joint was played by the muscles around it The success of this operation has shown that a useful hinge-joint can be substituted for the elaborate array of semilunar cartilages, crucial ligaments, and synovial membrane, provided always that the muscles are strong and active

STUDIES IN VITAMIN B

Important among the experiments in nutrition carried out during the past year at the Lister Institute of Preventive Medicine[1] were a number on the water soluble B vitamins, their isolation, heat stability, distribution and components. Dr Harriette Chick and Miss Copping who have been engaged in attempts to prepare concentrations of vitamin B 2 from egg white, in which it occurs unaccompanied by vitamin B 1 and from mammalian liver, have also taken part with Miss Roscoe in a quantitative study of the heat stability of vitamin B 2 in yeast and yeast extracts and of its sensitivene s in the presence of alkali. In acid solution, with the *p*H maintained at 5, no lo s in potency could be detected after incubating for two hours at 90° to 100° C., but 50 per cent. loss occurred after incubating an acid solution (maintained at a *p*H of 5·0 to 3·0) from four to five hours at a temperature of 123° C. When the reaction was alkaline—namely, with a *p*H of 8 to 10—the loss of potency was 30 per cent. after ten days at room temperature 50 per cent. after two hours at 90° to 100° C., and 75 to 100 per cent. after four hours at 123° C. The same results were obtained whether the assay of residual vitamin B 2 was carried out by studying its growth promoting effect when added to an experimental diet deficient only in this vitamin, or its potency in curing the specific skin lesions developed on such a diet. The conclusion derived from these experiments—namely, that vitamin B 2 is thermo-sensitive in the presence of alkalis—is opposed to that of other workers in this field, who consider that vitamin B 2 is stable in the presence of alkalis at high temperatures, but that yeast contains an additional factor, vitamin B 3, which is thermo- and alkali labile. According to Dr Chick and her co-workers, evidence of the existence of a third, hitherto unrecognized, dietary factor in yeast has been accumulated in the course of their research, but this factor seems to be thermo-stable. Young rats, they have found, do not grow so well on synthetic diets in which vitamin B 1 is provided by Peters's concentrate and vitamin B 2 by egg-white as they do when the B 2 is furnished by autoclaved yeast products. Further, their repeated failure, experienced in common with other workers, to breed from rats reared to maturity on diets containing all the recognized B vitamins and other dietary factors also suggests the existence of at least one unknown factor that is indispensable for correct nutrition. Search for this unknown factor is being made among both purified substances and ordinary foodstuffs. Meanwhile Miss Roscoe has extended the study on distribution of vitamin B 1 and B 2 in natural foodstuffs to green and root vegetables, and has found lettuce, cabbage, and spinach to be valuable sources of B 2, and much richer in this substance than in B 1. Dr Aykroyd and Miss Gaffikin are extending on a large scale previous work on cereals—namely, wheat, rice, maize, millet, and their constituent parts, with the object of throwing further light on the epidemiology of pellagra. Foods rich in vitamin B 2—for example, meat, milk, eggs, and green vegetables—are just those which have been found most effective in the prevention and cure of this disease. Cereals as a class, however, are poor in this vitamin, but as pellagra is confined almost entirely to maize eaters and is hardly known among populations whose staple food is wheat, rice, or millet, the hypothesis that lack of vitamin B 2 is the primary cause of the disease should be easily tested by assays to discover if the vitamin B 2 content of milled maize is or is not appreciably lower than that of the other milled cereals. The cereals mentioned are also being assayed for their vitamin B 1 content in order to test the vitamin B 1 theory of the etiology of beri beri.

[1] Report of the Governing Body 1930.

THE BANTING INSTITUTE.

The University of Toronto, already the possessor of some beautiful and commodious buildings, has lately been doing much to enlarge its accommodation and extend its amenities both for teaching and for research. In these extensions the needs of the great Toronto General Hospital and of the crowded Royal Ontario Museum, are being borne in mind. By a happy combination of circumstances the latest achievement in this direction, the opening of the Banting Institute took place on September 16th last at a time when a large number of members of the British Medical Association, returning from their tour to British Columbia, were in the city. The building has been erected under the joint auspices of the Board of Governors of the University and of the Board of Trustees of the hospital. It stands just across College Street from the hospital, and the two institutions are connected by a spacious underground passage. It is the university's pathological building, and provides, on six floors with basements not only lecture rooms, library, museum, and research laboratories with quarters for animals but also for most of the hospital laboratories, test rooms, and pathological services. It was thought wise to associate the building with the name and work of Dr Banting, whose particular quarters now occupy its fifth floor. The opening ceremony was performed by Lord Moynihan, who gave a brilliant address to a very large and distinguished gathering in the University's Hall of Convocation at Hart House, after a considerable number of representatives of universities and colleges from all over the world had been officially received. Many of these were members of the Association's tour. The ceremony concluded with the unveiling of a portrait of Lord Lister, which, by a piece of excellent management, was found in its proper permanent place over the mantelpiece in the library of the Institute when the company proceeded to inspect that building. Later in the day the honorary degree of LL.D. was conferred on Lord Moynihan, together with three others, and there was a garden party, for which, however, the weather proved unfavourable. At night, in the Great Hall of Hart House, a dinner was given by the Governors of the University. The chairman was the Hon. and Rev. H. J. Cody, the chairman of the Board, and all the male members of the British Medical Association party were among the guests. The toast of "The University of Toronto" was proposed by Lord Moynihan, and responded to by Dr. A. Primrose, a vice-president of the Association and dean of the Faculty of Medicine in the University. Professor Robert Muir, with others, responded to the toast of "Sister Universities," and Professor A. H. Burge who represented the Royal College of Surgeons of England, Sir William Taylor, Dr Robert Hutchison, and Sir Ewen Maclean expressed the thanks of the guests. There seems a tendency in Canada to enjoy a flow of oratory. On this occasion it was abundant but excellent. The University of Toronto is to be congratulated not only on the new building itself, but upon its very brilliant and successful inauguration.

INTERNATIONAL CONGRESS OF THE HISTORY OF MEDICINE.

The eighth International Congress of the History of Medicine was held in Rome from September 22nd to 28th under the presidency of Dr Pietro Capparoni professor of the history of medicine at Pisa. There was an attendance of about 250 members from fourteen different countries. The British delegate was Dr J. D. Rolleston, who also represented the Royal College of Physicians of London and the Royal Society of Medicine. Professor C. E. Gask represented the Royal College of Surgeons of England and the University of London, Dr Vincent

Dickinson the Society of Apothecaries Dr R Whitehead the University of Manchester, and Captain P J Johnston-Saint the Wellcome Historical Medical Museum The meetings were held in the Accademia dei Lincei, where three principal subjects were discussed The first was the protection of Europe against leprosy in the Middle Ages, which was opened by Professor Jeanselme of Paris, followed by Drs Veronica Gomom, Tricot-Royer, Carvalho, Torkomian Pizzini and Hult, who dealt with the incidence of leprosy in Rumania Belgium, Portugal Armenia, Rome and Sweden respectively The second theme was the medical and scientific relations between Italy and other European countries during the Renaissance, which was introduced by Professor Castiglioni, professor of the history of Medicine at Padua, and continued by Professor Sudhoff of Leipzig Dr Unger of Amersfoort, Dr Pomom of Ancona and Dr Carvalho of Lisbon The third subject, which was the question of making the study of the history of medicine compulsory in medical faculties, was introduced by Dr Ladislav Szumowski of Cracow, in which Professor Koch of Frankfort Professor Diepgen of Berlin, and Dr Legrand Laurent of Paris took part The congress came to the conclusion that this subject should be made compulsory and that a notice of this decision should be sent to the various Governments represented at the congress Among the large number of other papers on various subjects may be mentioned those on the relations between the Accademia di Cimento and the Royal Society, by Dr Mosè de Segni Nicolas Steno, by Dr V Meisen, the appearance of chlorosis in the sixteenth century, by Dr Axel Hansen, malaria in contemporary poetry from Virgil to Carducci, by Signora Anna Celli, and Girolomo Cardano and Leonardo da Vinci by Professor Balanzoni The only British contributions were those on madder in the history of medicine by Dr G R Cameron and a rare Jewish medical curiosity of the eighteenth century, by Dr D A H Moses The receptions included an audience and address by the Pope visits to the Bibliotheca Casanatense and Bibliotheca Lancisiana, and excursions to Lake Nemi and Monte Cassino, where a bronze was presented to the monastery in recognition of its services to medical science during the Middle Ages No effort was spared by the authorities to make the foreign doctors and their families feel at home in the Eternal City, and until the last evening, when Jupiter Pluvius became active, the weather remained ideal During the congress Professor Giordano of Venice was elected president of the International Society of the History of Medicine in succession to Dr Tricot-Royer of Antwerp, who has held office since the foundation of the society in 1921 The next congress will be held in Bucarest in 1932

THE DISCOVERY OF TRICHINA SPIRALIS

The recent outbreak of trichinosis in Stuttgart has kindled interest in a disease epidemics of which are uncommon in this country The story of the discovery of the parasite[1] is obscured by priority claims which lack historical perspective Even the new edition of Osler's *Principles and Practice*—a textbook famed for its historical atmosphere—gives a regrettably incomplete account of the history of trichinosis, with no mention of Paget's name The main events in the story may briefly be summarized F Tiedemann in 1822 was the first to describe "white stony concretions" in human muscle (analysed by L Gmelin), though he never suspected their parasitic origin In 1833 John Hilton described minute cysticerci in which microscopically he was unable to detect any organization On February 2nd, 1835, at St Bartholomew's Hospital, James Paget was dissecting the muscles of a subject when his scalpel became quickly and repeatedly blunt Other students had attributed their similar experience to the presence in the muscles of "spicula of bone," and Wormald, the senior demonstrator of anatomy, had seen at least twenty bodies studded with whitish specks Paget, however, was the first to suspect their animal nature, which he confirmed with the aid of Robert Browne's simple microscope—for St Bartholomew's did not even possess a dissecting lens He made careful sketches of the worm, preserved in the library of the Royal College of Surgeons of England, and lectured on his discovery to the Abernethian Society of St Bartholomew's Hospital, on February 6th On Stanley's suggestion he wrote an account of his work for the *London Medical Gazette* This was never published, but the manuscript may be seen at the College of Surgeons A specimen of infected muscle was sent to Richard Owen, who established the nematoid nature of the worm, named it *Trichina spiralis*, and, taking the credit for its discovery earned the applause of his professional brethren Paget's behaviour in this melancholy episode was admirable His original specimen was deposited in St Bartholomew's Hospital museum Fifty years later it was thrown away as time had reduced it to dust and ashes The life-history of the *Trichina* was fully worked out by Herbst Virchow, Zenker, and Kuhne, who completed a discovery made by a medical student of twenty-one years

[1] Fully told in *St Bartholomew's Hospital Journal* 1928 xxxv, 39–42.

MANY INVENTIONS.

Mother Necessity has had a fertile season, to judge from the 500 new inventions which have been on view during the last ten days at the Central Hall, Westminster, under the auspices of the Institute of Patentees Those who are of an inventive turn of mind are fortunate in having this body to assist them in developing their ideas for they themselves can remain anonymous if they wish, while their productions are assessed by the critical eye of the public, including prospective patrons Some of the devices are charmingly ingenious Goldsmith's chest of drawers which contrived a double debt to pay, is wholly outdone by a piece of furniture which can serve ten different uses What occupant of a flat or bungalow is not attracted by having a bath-tub, a cot, a desk, a dinner wagon, a settee, and five other things all in one turn-about piece? Then there are such domestic helps as a thief-proof milk bottle holder, a dripless teapot, a water-cooled food safe, and an effective draught-excluder Men should welcome a collar-stud which refuses to be lost, perhaps also a tobacco pipe designed for wearers of dental plates, and a watch glass which allows notes of appointments to be written against the hour For golfers there is provided a means of producing a perfect sand tee of standard height, and for sunbathers a garment which uncovers sections of the body in turn the rest remaining veiled Only one device, so far as we can see, aims at diminishing the risks of the most dangerous of all pursuits, that of the pedestrian, this is a small mirror which, suspended from the hat brim, enables the wearer to see what fate is overtaking him from behind But the brains of the inventor have been hard at work in the interests of the motorist, for whom there are any number of automatic signalling devices for use at cross roads, antidazzle headlights, a number plate which at night acts also as a rear light, a lavatory attachment for a motor vehicle, various improvements in shock absorbers and sparking plugs, also a thief-proof device which gives an alarm if the car is started up by an unauthorized person One sanitary innovation of interest is known as the "cindor" closet, designed to effect the destruction of refuse by electrical heating It is claimed for this appliance that it eliminates the need for drains or cesspools, there is no sewage or sewage air, and it is

independent of water which is a consideration in the country where water for sanitary purposes may not be abundant With the bringing of electricity to the remote villages some contrivance of this kind may serve a useful purpose in domestic sanitation in country districts

AN INTERNATIONAL CIVIL SERVICE.

THE most protracted debates in the League Assembly continuing to the very end of the session (writes our Geneva correspondent) have concerned what might seem to be a domestic matter A committee of inquiry—known rather ominously as the Committee of Thirteen—has been considering for a year the reorganization of the Secretariat of the League and the International Labour Office It has made certain proposals for reform and a minority of its number has approved more far reaching recommendations Two "school of thought" have revealed themselves as sharply opposed on a point of principle One the majority led by the British delegation has taken the view that those who enter the service of the League of Nation should be in every sense of the word international officials owing no allegiance to any Government or authority external to the Secretariat The other the minority of which Italy has been the most vocal, appears to think that officials should regard themselves as nationals and as representatives of their country During the eleven years history of the League the organization has been of a provisional character but it has been evident that under the able leadership of the Secretary General Sir Eric Drummond, a body of good international officials could be reckoned upon whose loyalty to the League was beyond question It has been felt however that the time has come to set up an international civil service based upon the recruitment of some of the best young men and women from all countries to serve the League of Nations There has also been some jealousy among the smaller nations because hitherto the five officials of the high direction of the League have been nationals of the Great Powers The British delegation has shown its concern to remove any sense of injustice and to throw open even the highest post to the members of the smallest nation As a result of the debates the minority proposals which aimed at vitiating the authority of the Secretary-General have been turned down some of the more radical majority proposals have been deferred for a year, while other interior reforms are going forward When the new scheme is in existence the principal officers of the Secretariat will consist of the Secretary-General, a deputy, eight under secretaries-general, and six directors The work will be distributed among fourteen sections, each under an under secretary-general or director One of these is the Health Section, and another the Traffic in Opium and Dangerous Drugs Section which henceforth is to be separated from the section dealing with social questions There are about 500 permanent posts in the Secretariat, and 400 in the International Labour Office, but besides these there are many temporary posts, especially in the Health Section where highly expert persons often enter the League's service for three or five years to do specialized work required at the moment The minimum age for permanent appointment is to be 23, and the maximum 35 but the Secretary-General is empowered to make exceptions The compulsory retiring age will be 60, and after a long struggle it has been decided to inaugurate a pensions scheme The salary of directors is to be (we translate it roughly into English currency), £1,760 rising by annual increments of £104 to a maximum of £2,200 They will be appointed for seven years, and their appointments will be renewable The salary of members of sections will begin at £500 and proceed by annual increments of £33 to a maximum of £1 150 With regard to temporary members of sections, the Secretary General is free to fix their salaries in the case of engagements for less than five years in the case of engagements for a longer period he is to be guided by the rules laid down for permanent officials A very important consideration is that permanent officials are exempt from income tax whether temporary officials are exempt is a matter of controversy

PIONEERS OF PUBLIC HEALTH

UPON the façade of the new building of the London School of Hygiene and Tropical Medicine are displayed the names of certain of the great who first explored the fields of public health The main facts regarding the lives and work of those distinguished men have now been set forth by Mr M E M Walker in a pleasing book appropriately entitled *Pioneers of Public Health*[1] For the names selected the author is not responsible they were chosen by a committee, and Sir Humphry Rolleston observes in a preface that some might have been inclined to head the list with Hippocrates instead of Sydenham The remaining names are those of Sir John Pringle James Lind J P Frank Edward Jenner, Lemuel Shattuck Sir Edwin Chadwick, William Farr, Sir John Simon, M. von Pettenkofer Edmund Parkes, Louis Pasteur, Lord Lister T R Lewis, Robert Koch, Sir Patrick Manson Alphonse Laveran, Walter Reed, General Gorgas, Hermann Biggs and Sir William Leishman, pioneers in military, naval, and civil hygiene, in bacteriology and parasitology, and in the prevention and treatment of disease in home and foreign fields The book, which is lucid and informative, may be recommended as a concise survey of the endeavours and achievements of these benefactors of the human race

SIR HUMPHRY ROLLESTON, Bt, will deliver a public lecture at 5.30 p.m. on Wednesday, October 15th, at King's College University of London, on "Medicine as a career" All interested are invited to attend

THE eleventh Maudsley Lecture will be delivered before the Royal Medico-Psychological Association by Mr Justice McCardie in the Great Hall of the British Medical Association House Tavistock Square on Thursday November 30th at 3 p.m. The title of the lecture is "Truth"

BY special invitation of the council Dr Chevalier Jackson of Philadelphia will deliver a lecture before the Royal Society of Medicine on Tuesday next, October 14th, at 8.30 p.m. entitled "Suppurative diseases of the lungs" The lecture will be illustrated by cinematograph films, slides and chalk drawings executed during the lecture

THE Schorstein Memorial Lecture will be delivered on Friday, October 17th, at 4.15 p.m., in the Barsted Clinical Theatre of the London Hospital by Mr H S Souttar The subject is "Radium in the service of surgery" Members of the medical profession are cordially invited to attend

WE regret to announce the death on Sunday last of Mr A L Whitehead F.R.C.S. consulting ophthalmic surgeon to the Leeds General Infirmary An obituary notice will appear next week

[1] *Pioneers of Public Health*. By M. E. M. Walker. With a foreword by Sir Humphry Rolleston Bart., G.C.V.O. Edinburgh and London: Oliver and Boyd. 1930. (Illustrated. 12. 6d. net.)

Opening of the Winter Session.

SURGERY IN THE IMMEDIATE FUTURE

Address to the Guy's Hospital Medical School

BY

LORD MOYNIHAN,

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS

An Irish poet has written,

> 'Each age is a dream that is dying
> Or one that is coming to birth'

In surgery we are approaching the end of one age, and already see the opening of another. The present epoch began on August 12th, 1865 when Lister for the first time applied a carbolic acid dressing to a compound fracture. There is no need to recite once again the changes wrought by Lister in the world of biology and in the world of surgery which he created anew. Lister's work in biology was the necessary and inevitable corollary to Darwin's. The enunciation of Darwin's hypothesis was beyond doubt the most important intellectual event of the nineteenth century, and the most fruitful that had ever occurred in the history of biology. Its inherent ideas, though seeming so revolutionary, were already overdue. The biological sciences, overburdened by unassimilated facts, had fallen into a drowsy torpor of repletion, and were ripe for an enlivening stimulus, for the "flash of lightning in the darkness" as Huxley said. Yet the hypothesis was incomplete, for the environment known to Darwin in respect of the physical and animal worlds was quite inadequate to bring about the effects he attributed to it. To the physical elements man by his long subjection to them and his wide adaptability, based upon stubborn though silent defence, had become inured, and the known animal world was already in subjection. It was the work of Pasteur and Lister which completed the hypothesis by showing that man's most dreaded enemies were invisible, surrounding him on all sides, and that their number, varieties, and infinite versatility in attack, were the most impressive and the most powerful of all agents in his environment. Lister was not only establishing new methods, but was also asserting a new biological principle of the highest significance.

Lister's work for surgery made the old operations safe; it gave us the opportunity to invent a multitude of new and far more extensive operations, it created luminal research, and it enlarged the scope and increased the practice of animal research. It has therefore enabled us in pursuit of operative methods for the cure of visceral disease, especially of disease above and below the diaphragm, to observe the condition of organs during life, to study disease in full career rather than at the end of a long and destructive journey, and little by little to discover and describe the symptoms aroused and the signs produced by such disease in earlier and still earlier stages. So far as animal research is concerned the physiologists with this new weapon have added knowledge of great value in connexion with the function of many organs.

In the progress of modern surgery its practitioners have had to rely chiefly upon themselves. I have made the claim, and I have been criticized for so doing, that surgery, in so far as its craft is concerned, has now almost reached its limit. I am unmoved by my critics, and I venture once again, and quite impenitently, to assert that the statement is true. The full fruit of Lister's work in relation to surgery has now been gathered. Almost every organ in the body has been made accessible to the surgeon; operations upon these organs can hardly be extended in the future; they are to-day performed with a degree of safety which, in the hands of the few great masters, can be little, if at all, surpassed. So long as the stomach, or portions of intestine, must be removed for cancer, the gall-bladder attacked for calculous disease, a lobe of the lung excised for neoplasm or for bronchiectasis, the heart itself opened to remove a foreign body or closed after the infliction of a wound, the brain or spinal cord approached to deal with any of the diseases which attack them, the operations practised can hardly be safer than they already are in the most expert hands to-day. The craft of surgery has in truth nearly reached its limit in respect both of range and of safety. We may find other and safer methods of dealing with disease, we may obtain earlier access to acute or malignant conditions, we may find that the application of radium to organs, accessible but irremovable, may render unnecessary the mutilations of surgery, but we can surely never hope to see the craft of surgery made much more perfect than it is to-day. We are at the end of a chapter.

What has been the main effort or the gross result of the labours of this last sixty-five years in the field of surgery? Speaking generally, surgeons have been concerned with the recognition of structural changes in visceral disease, and in the invention of operative methods for their removal or relief. The operations practised have been mechanical methods of removing, checking, or circumventing mechanical disabilities. The efforts of surgeons have been triumphantly successful. Indeed, in many instances, with which physicians continually remind us that they are familiar, this very success has proved the direct cause of grave disaster. When gastro-enterostomy, for example, became standardized, and fell within the competence of anyone with trained hands, and when its success was so great that perhaps no other operation ever practised could surpass it as saviour of life and giver of health, then, unhappily, the indications for it became extended, both by physicians and by surgeons, to a grossly illegitimate extent. Evil results soon followed, and an operation of the greatest value became discredited. It was not the operation which called for criticism and disparagement, but rather the operator, whose lack of knowledge or discernment dishonoured the cause of surgery. These surgical excesses produced an inevitable reaction. Nothing but a reckless and unjustifiable extension of surgical methods in the treatment of dyspepsia would have allowed, or may condone, the recent recrudescence of medical treatment in cases of chronic inveterate gastric or duodenal ulcer for which it is unsuitable, and dilatory and dangerous. The recent report on the methods revived by MacLean at St. Thomas's Hospital will disappoint all who had based strong hopes upon them. The errors of surgical excess are lamentable enough, but the errors of medical excess are more serious. The deaths from haemorrhage, perforation, or malignancy after the "cure" of peptic ulcer compel us to realize how much more dangerous, how much less trustworthy, are the methods of medicine than are those of surgery. It is the redundance of surgery which belittles its triumphs and encourages the fanciful but untenable claims of medicine.

If then surgery, as a mere mechanical craft, can hardly go further, what is to be its future? In what direction may we expect the new adventures to be launched? Surgery since Lister's day has, as I say, been concerned not only in the rescue or relief of our patients, but in the creation of new knowledge, in the refutation of ancient error long accepted upon high authority, in research into the interrelation of visceral diseases, and into questions concerned with their causation. As a therapeutic weapon and as a research weapon it must still continue. It is not difficult, however, to realize that a change in its objective is already apparent. It has been the power by which structural disorders have been overcome by mechanical means, and its strength has been derived from deep foundations in anatomy. It is becoming, and will increasingly prove to be, the agent by which control is gained over disorders of function, and its strength will derive from physiology.

The progress of physiology in the last century has been formidable and beneficent. It was born again by fission in the days of Sharpey and his pupils. It drifted away from descriptive anatomy, the science of the structure, ancestry,

and variations of man's body It attracted the eager and inquiring minds not only from within our own profession, but in very notable instances it enlisted the help of men who owed no allegiance to medicine Its growth both in respect of rapidity and range was stupendous, almost passing belief But little by little, very insidiously its character was changing and its interest in man becoming more and more remote I have said of it without any desire to be cruel—for a compassionate heart is my life's handicap—that physiology is no longer entitled to the name it bears It has made alliances with physics and chemistry, so close, so interwoven, that its identity is in danger, and may be lost Its true mission which was to elucidate the problem of the normal function of man's organs, is less and less considered Nominal physiology indeed, has awakened or sustained an interest in few physiologists, whether at home or abroad It is true that they have been busy in the practice of animal research, but not seldom their labour has seemed aloof from human problems, and the results incapable of application to the maladies of men If we are to profit by the work of the laboratory in the immediate future physiologists must concern themselves more and more with human afflictions, and especially with those conditions which approximate so closely to the normal that only expert investigation as to normal conditions is competent to discover or appraise them If those who now hold the chairs of physiology in our teaching schools cannot be attracted to the study of man it is time to consider whether we should not now seek to establish chairs in human physiology giving those appointed the right of access not only to hospital beds, but, what would be far more valuable, to the out patient room, where the earlier stages of disease are seen The truth is that we are all far too much concerned with advanced or at least with firmly established, disease There are earlier phases of disturbed function which lead up perhaps very slowly to those gross conditions which afflict the hospital in patient, and, indeed, alone justify his admission The physician or surgeon on the full staff of a hospital is our last line of defence, fighting in the last ditch It the moment this is right and proper indeed inevitable but are we not as a profession capable of something better than this Can we not create an advance guard Can we not fight at the outpost rather than, as we so often must in the very heart of a citadel, the outworks of which have been already captured If so we must create a vast body of new knowledge, and the only true begetters of this will be the men trained in laboratory work together with the clinician medical or surgical What is immediately required is a better knowledge of normal man, and of the 'near normal' abnormal man Physiologists are those best trained to acquire this almost non existent knowledge, and a new science of 'parapathology" needs to be brought to our aid The physiologist must however return from his journeys into a far country, and a warmer greeting than that which awaited the prodigal son shall be his We are grown accustomed to the plaudits which acclaim the work of physiologists in the last half-century I grudge them nothing but I cannot repress a feeling that they might have been much better occupied that if it has not been in riotous living they have nevertheless in some degree at least wasted their substance Our affection for them and our pride in their accomplishments, are however, inexhaustible but we need them at our own, at their own, hearthstone Surgery at least has not done so badly with only meagre help from them, but if, having completed one adventure we are setting out with far more assured competence and with equal enthusiasm, upon another we are confident that no progress commensurate with our opportunity can be made unless they guide us travel with us and inspire us This guidance has been lacking where it should have been insistent After the work of Gaskell and Langley we might at least have expected a hint as to the possibility of helping such conditions as say Hutchinson's disease or Raynaud's disease, by an attack upon the sympathetic nervous system The absence of a close affinity between laboratory worker and clinician has already is clear evidence of a lack of vision on the part of both and it is the sick who suffer from and bear the burden of our default The surgeon indeed must bring the science of structure and the science of function together after their long separation, he must create a union where Sharpey and his pupils made a clear division The work of Rose and Hunter, followed by Wade of Sydney Robertson of Toronto, Adson, and Learmonth have shown how very diverse maladies are capable of relief by a surgical attack upon the sympathetic nervous system Much remains to be done not only in anatomical and physiological research but in its application to various diseases of man along the lines they have laid down What part, we may hopefully ask, does the abdominal sympathetic nervous system play in those remaining functional disorders which, formerly so numerous, have now been so greatly reduced by successive victories of the surgeon? What is the significance in colons removed for dysfunction, of those interesting changes found by Keith in Auerbach's plexus? Why have the adrenal glands so unexampled a relationship with the sympathetic system? And so on In the immediate future surgery will be interested in, and perhaps concern itself with, the sympathetic and parasympathetic nerves in the neck, chest, abdomen, and pelvis with intrathoracic diseases with ductless gland and with questions of immunity Will the physiologists return home in time to help us? Their activities have been those of the gymnasium rather than of daily life, impressive, but of an unrelated to useful purpose

The new outlook of surgery which I have foreshadowed may suggest that, in order that he may be better equipped for his work a change in the training of the student of medicine is desirable I think it is The chief instrument which the student and the practitioner must bring to bear upon the grave problems which will confront them in their professional careers is the mind Is it not worth while to train this in some preliminary way in order to increase its efficiency and adaptability? In the old days an examination in logic and psychology was held at the completion of one's career at the London University Why not at the outset rather than at the end The logical processes of induction and deduction, of observation and experiment, are most necessary elements in everyday work in medicine yet no instruction in their meaning or usage is at any time vouchsafed Any physician or surgeon who has taught students must admit that very few of them have any idea at all as to the way in which their minds should be applied to medical problems The chief business of the student is acquisition Like Mr Gradgrind he is greedy for facts, but he is oppressed by their number and their needless and intolerable complexity He is given information rather than understanding He does not know how to assimilate the multitude of facts so different in kind from other facts which he has acquired at school or university He does not in truth know how his mind works nor what an excellent instrument it may become with proper discipline and training How soon philosophy should be taught I cannot hazard an opinion but it is so surely the very foundation of all things that the earlier some acquaintance with it is made the better for us all The life of the student should be made more interesting and the life of the practitioner more fruitful if the study of anatomy could be regarded as a method of mind training no less than a method of acquiring knowledge of man's body, if physiology were regarded as the earliest and best opportunity of training the mind in the methods of experiment, and if the method were practised and exhibited not in the laboratory only but in wards and operation theatres also In training the student we cannot possibly give him all the knowledge he requires (that is a state to which none of us ever attain) but we can make his task easier and his life of more value if we train him in method, so that he may know what to look for where to seek, and how to appraise so that he may observe discriminate and test

A further and even more important change made necessary by the new outlook is concerned with the creation or strengthening of mechanisms to secure close cooperation between research workers and clinicians The Medical Research Council which might exert so ministerial and so inspiring an influence upon the progress of medicine—the very purpose surely, for which it was founded—seems too

busy with little things, too aloof from the day-to-day practice of medicine, out of touch with the needs and desires of clinicians It is hardly credible that in the last annual report such questions as these could be asked "Is there a science of experimental medicine of which the actual material for study is the human patient? Or is scientific work by the physician or surgeon limited to the application in his art of scientific results worked out elsewhere in the laboratory and delivered to him for use?" What is scientific work in the practice of physician or surgeon? It is surely the making of accurate observations, the testing of those observations by all appropriate methods, discriminating as far as possible between truth and error, the collection and correlation of such observations, until at last from them a general truth may be formulated In experimental medicine these observations are made upon human material," upon patients whose symptoms receive exhaustive inquiry, with infinite patience and with consummate skill the phenomena observed are freed from manifold [illegible] other causes, and the constantly shifting [illegible] both the temperament, the mood, and the [illegible] of the patient mingle with truth Inquiry, however complete and unassailable, must be repeated until error is at last eliminated The physical signs of disease are then studied by every available device, including operation The evidence afforded by ancillary methods of inquiry by bacteriologist, biochemist, radiologist—are first appraised (a very necessary precaution), and when acceptable are ranged with clinical evidences, each separate contribution being given its exact value and placed in right perspective When this full inquisition has been carried out the qualities of the disease and their organic cause may be recognized When this procedure is often repeated it is true to say that new knowledge has been created If this is not "scientific research," then words have no meaning Clinical research of this kind differs from research work in the laboratory only in difficulty in infinite complexity, and in the graver responsibilities which attach to it

The questions I have quoted from the annual report of the Medical Research Council suggest that the work of the physician is a mere synthesis of the work of others It is certainly that, but it is much more What have laboratory workers done to help us in the recognition of such a disease as gastric or duodenal ulcer, infections of the gall-bladder and cholelithiasis, splenic anaemia, haemolytic jaundice, to mention some of the diseases with which I am very familiar? What could they do when such diseases do not exist apart from man, when only the "actual material for study is the human patient"? If the first edition of Fagge's *Textbook of Medicine*, the best of all textbooks of its time is searched, the title "duodenal ulcer" will not be found even in the index The greater part of our new knowledge of visceral disease has been created by clinicians without any help from the laboratory The laboratory has been used, not for the discovery of new knowledge, but for its illustration

The truth is and I grieve to say it, that a grave disservice to medicine is suffered by the exaltation of the work of the laboratory in comparison with that of the wards and theatres Both are necessary the one is the corollary of the other The scientific mind and the scientific method are equally necessary in both In the report of the Medical Research Council it is said that most of this research work is conducted in the laboratories of physiology, biochemistry, bacteriology, pathology, and the like, and a "very small part of it has been done by men engaged in clinical work and studying disease as it actually presents itself in human beings" This sort of opinion is only what we might expect from a Council so imperfectly constituted Of its twelve members, one only, and he the most recent appointment (the very best possible) possesses *any adequate knowledge of scientific clinical surgery*, one only practises medicine, and his very able mind sways rather to the laboratory than to the wards The Council, as a body, is little possessed of any power to understand the nature of clinical problems, and appears to display little interest in them The report says, "It is important here to draw at once a clear distinction between the work of the physician engaged in practice and the work of a man engaged in the task of advancing knowledge" I beg anyone who reads this sentence to reflect upon it for a moment and then to ask himself how much our knowledge of visceral disease has not only been advanced, but both created and advanced, by those engaged in practice, and it is almost true to say, by no one else The suggestion that the physician engaged in practice does not advance or has not advanced knowledge will be read with consternation by all those who have any slightest knowledge of the history of medicine

The attitude of the Medical Research Council condones, if it does not encourage, that estrangement of physiologists from human problems for which, of course, it was not primarily responsible What is now most urgently needed in medicine is a consolidation of the forces attacking the manifold problems of disease The leadership which the Medical Research Council, newly constituted, might give, would be of inestimable advantage But the Council must either have a larger representation of clinical medicine and surgery, or call practitioners to its aid in an advisory capacity With the knowledge and new vision which clinicians would bring research would be attended by more fruitful and more relevant results At present the Council seems to apply not ungeniously the system of the dole, giving here a little grant, and there a little but evidence of a controlling, constructive, and unified policy is lacking I find that many physicians and surgeons engaged in the active practice of our profession read the annual report of the Council not only with dissatisfaction but with regret that so little appears to be known to its compilers as to the position and needs of the practice of medicine in any of its branches In the future medicine must march in closer companionship with its most valued allies, of whom there are many Every individual and collective effort will be needed At present our efforts are too disparate and disjointed It is our plain duty to realize that one principle should guide and sustain us all, that we must take counsel together, each learning what the other is doing, and testing and applying our knowledge, wherever it appears to be relevant

ST BARTHOLOMEW'S HOSPITAL.

OLD STUDENTS' DINNER

As usual, the new session at St Bartholomew's Hospital was inaugurated with the old students' dinner, which was held on October 1st, in the Great Hall of the hospital The chairman on this occasion was Mr L Bathe Rawling, surgeon to the hospital, he was supported by the Lord Mayor and the Sheriffs of London, Lord Stanmore, treasurer of the hospital, and other members of the governing body, Sir John Rose Bradford, P R C P , Sir Holburt Waring, Air Vice-Marshal Sir David Munro, the head master of St Paul's School, the Masters of the Cloth workers', Farriers', Haberdashers,' Mercers,' Salters,' and Skinners' Companies, Surgeon-General P H Benson, I M S (ret), and members of the visiting medical staff

After the Royal toast had been honoured, the chairman described the progress of St Bartholomew's during the thirty-six years of his association with it He paid a special tribute to the late Mr C B Lockwood, who had been a pioneer as regards securing reconstruction of the hospital, and Sir Holburt Waring, who had continued the campaign triumphantly after the war A new era in the history of the hospital had begun with the erection of the nurses' block, followed by the series of improvements, until the present, when the magnificent surgical block and theatres had come into being In commemoration of Sir Holburt Waring's work one of the new surgical wards had been named after him The Lucas block, including the Abernethy and the ophthalmic wards, had now been handed over to the obstetrical and gynaecological departments Theatre A, which had been renamed in memory of Raymond Etherington-Smith, was now devoted to gynaecological and obstetrical operations, and the old ophthalmic theatre had become the Williamson laboratory Further improvements were contemplated, these including a new medical block, residential accommodation for students,

blocks for paying patients and for x-ray work an up-to-date anatomical department and the reconstruction of certain special departments. Paying a tribute to some whose connexion with the hospital had been severed during the preceding twelve months, Mr Rawling commented particularly on the loss sustained by the departure of Dr T. W. Shore, for many years dean of the Medical College. Sir CHARLES GORDON WATSON proposed the health of the Lord Mayor, and this was drunk with musical honours. A short speech was made also by Surgeon-General P. H. BENSON, who was a student at the hospital in the early seventies.

CHARING CROSS HOSPITAL

OPENING OF LOCKYER COLLECTION

THE annual prize distribution and inaugural address at Charing Cross Hospital Medical School on October 4th were preceded by the opening of the Lockyer collection of obstetrical and gynæcological specimens in the museum in Chandos Street, W.C. This collection, numbering nearly 2,000 specimens and suitably housed in a large double-galleried hall, is the generous gift of Dr Cuthbert Lockyer, consulting obstetric physician to the hospital.

Mr GEORGE VERITY, chairman of the hospital, in presiding, said that this was one of the greatest occasions in the history of Charing Cross Hospital during the twenty-five years of his own association with it. Dr Lockyer had performed a great act of munificence by the presentation of this marvellous collection, the result of many years' painstaking effort. In addition to the actual specimens he had provided an equal number of slides illustrating them, which were contained in a special cabinet. He had also written and published at his own expense a detailed catalogue of the exhibits, and had invested with trustees the sum of £500, the interest on which was to be spent on the upkeep and repair of the collection.

Dr CUTHBERT LOCKYER, in response to an enthusiastically accorded vote of thanks, said that he was indebted to his fellow consultant at Charing Cross, Dr William Hunter, thirty years ago for instruction in what was at that time a modern method of preserving specimens, and Dr Hunter had watched and encouraged the growth of this collection year by year.

Dr WILLIAM HUNTER said that the gift was made very appropriately this year, which was the centenary year of the school. It was, in his judgement, the most important collection ever brought together by one person since the days of John Hunter, whose collection was the basis of that of the Royal College of Surgeons.

The wide range covered by the specimens, and their admirable mounting, elicited many expressions of appreciation from the large company present.

INAUGURAL ADDRESS BY DR MACLEOD

An adjournment was then made to the hospital, where in the board room, the annual prize distribution took place. Mr LEIC A. CROOK, the dean, in his report said that the entry during the twelve months was double that of the previous year. Classes had been instituted in applied anatomy and physiology, with the object of linking together these preliminary subjects and actual hospital work. Surgical consultations had been instituted whereby it was possible for members of the surgical staff to consult with their colleagues in difficult and obscure cases. The patient's own family doctor was invited to be present, and the students attended the meeting. The post-graduate courses had been very well attended, the number amounting to 118.

Dr J. M. H. MACLEOD, after distributing the prizes and certificates, congratulated those whose work had been crowned by such awards. He recalled that one of those who were prize-winners in his own years had achieved great distinction in after life, but for the encouragement of those who had not gained prizes he might add that other prize-winners had been out-stripped by those whose student career was much more humdrum, and who were known as "the bloomers."

The study of medicine, Dr MacLeod said, has been compared to a maze in which the student wanders about hither and thither, meeting disappointments and difficulties, but at length emerging. A much better simile, he thought, to compare the study of medicine to a voyage in an ocean-going steamer, for after all the student of medicine is an intrepid adventurer going out to traverse wide oceans and exploring new land. During that voyage he is bound to meet with head winds and adverse tides, but at the end of all the buffetings he eventually gets to port. During the voyage, he has had the inestimable advantage of mixing with his fellows, for certainly learning is not everything in connexion with success in medicine. It is equally important to develop character, which can best be done by exchange of ideas and clash of personality. One hears on every side murmurs that somehow or other in this and other countries certain standards which the older among us have reverenced and thought likely to be permanent have been rather set aside, and some have felt that democracy and bureaucracy in medicine are apt to lead to a levelling down rather than a raising up. Well, you are fortunate in your voyage in having a happy ship, and whatever standards may be depressed we look to you with very confidence to maintain the standard of your school and the tradition of its past.

But the first port in any voyage is only a port of call, a coaling station, a port where you are fully commissioned for the larger voyage of your life's work, and as one of yourselves who has been through the greater part of that voyage I would remind you that success is not a matter of luck nor of genius, it is born of concentration, imperturbability under difficulties, patient thinking, and what old Dr Johnston called setting down to work. In your early days I would advise you to do everything you can to stimulate your imagination, so that you may be enabled somehow or other to estimate your own capacity, to find some individual aptitude, giving you a line of direction along which you may journey. Do not drift into things, for if you do that you may find yourself in the end in an uncongenial environment, a square peg in a round hole. Above all things avoid early rushing into specialism, but make every endeavour to get as wide a knowledge of medicine as a whole as you possibly can. In that way I can guarantee that you will achieve success, and before you reach the end of your voyage will be a credit to your alma mater, your teachers, and your school.

A vote of thanks to Dr MacLeod was voiced by Mr N. C. LAKE and Dr J. E. M. WIGLEY, both of whom expressed regret at Dr MacLeod's recent retirement from the active staff of the hospital. His association with Charing Cross will be maintained, however, as consulting dermatologist. Dr DAVID FORSYTH and Mr L. R. BROSTER spoke to a similar vote of thanks to the chairman, Mr G. VERITY, who in reply drew attention to one recent innovation at Charing Cross which represented a marvellous piece of civil engineering. When it was necessary to enlarge the casualty and out-patient departments it was found impossible to take in space to the right or the left or to go up. The problem was solved by scooping out the earth beneath the result being an ideal casualty and out-patient departments, four or five times the original size.

ST MARY'S HOSPITAL

ANNUAL DINNER

THE annual dinner of past and present students of St Mary's Hospital Medical School was held under the chairmanship of Dr JOHN MATTHEWS at the Trocadero Restaurant on October 3rd, when 130 sat down at the tables.

In proposing the principal toast, Lieut.-Colonel H. E. VEREY, chairman of the hospital board, stated that the contract for the rebuilding of the medical school and inoculation department had lately been signed. The work involved an expenditure of over £200,000, and had been made possible largely through the generosity of Lord Beaverbrook and Lord Rovelstoke. The rebuilding of the inoculation department would proceed concurrently with the rebuilding of the medical school, and he hoped that this, when completed, would form a worthy memorial to the work of Sir Almroth Wright, whose researches in vaccine

therapy had made St Mary's a household word throughout the world In spite of unparalleled industrial depression, the income of the hospital for the past year had exceeded its expenditure by some £3,000 The isolation ward had been reopened, but this had involved the uneconomical procedure of housing out a considerable part of the domestic staff It was proposed to erect on the remainder of the island site in Paddington a home capable of housing the number of nurses and domestic staff required for a hospital of 500 beds These departures were an integral part of the rebuilding of the hospital, for the 500 beds which it was extremely desirable to have in the interests of the school could not be worked without the necessary nursing and domestic staff, who should be able to "live in" The direction and control of the great London teaching hospitals did not become easier The Local Government Act would make great changes There were some who saw in it the prelude to the death of the voluntary system, which would mean an incalculable loss to the community He added a tribute to Sir John Broadbent, whose retirement is impending The hospital never had a more devoted servant, or one with a greater love for the place

Dr C M Wilson, dean of the school, in responding to the toast said that the enlargement of the hospital was the immediate task ahead The enlargement was essential from both the school and the hospital point of view The entry of students this year was exactly twice the entry in 1913 It was plain from the experience of the past few years that as a result of the present policy of St Mary's the entry could be increased to any figure which was desirable, but they were not so much concerned with numbers as with the type of men who entered the school Their policy was to limit the entry so that they were able to reject candidates for admission who, in their opinion, were not equipped for a medical career It was, they believed, better to have an annual entry of about fifty students than a larger number made up of everyone who applied for admission The school buildings and laboratories were being rebuilt at a cost of more than £200,000, and when this was completed in about twenty months, space would be set free for the enlargement of the hospital Their ideal was a medium-sized school for between two and three hundred students, who would be as far as possible picked men He thought this policy would ensure that a capable student would have no difficulty in obtaining a resident appointment on qualifying There was an unusually large proportion of Oxford and Cambridge men in the school, and in athletics the school was second to none St Mary's could claim that it had originated departures which had been widely followed elsewhere, such as post-graduate courses, affiliation with municipal infirmaries, and scholarship schemes

Mr Warren Low, in a happy speech, proposed the health of the chairman, Dr Matthews, one of Wright's earliest disciples who had done yeoman service in maintaining the fame of St Mary's as the Mecca of therapeutic inoculation

ST THOMAS'S HOSPITAL

OLD STUDENTS' DINNER

No formal ceremony was attached to the opening of the new winter session at St Thomas's Hospital, but the old students' dinner was held on October 3rd at St Thomas's House, with Dr R Muzio Williams in the chair He was supported by Sir John Rose Bradford, P R C P, Lord Riddell, Sir Arthur Stanley, Sir Ambrose Boyson, the senior almoner, Mr G Roberts ("Audrey"), two colonels—namely, Dr Ingleby Oddie and Dr A D Cowburn—with members of the hospital lay staff In proposing the health of St Thomas's Hospital Medical School, the chairman gave a series of interesting reminiscences of more than half a century ago, when he entered as a student He made special reference to such events as the introduction of the carbolic spray in surgery, and described how the students lived in those earlier days Sir Arthur Stanley (treasurer of the hospital) and Professor Dudgeon (dean of the Medical School) responded to the toast Sir Arthur Stanley remarked that this last year might indeed be termed a wonderful one as regards the progress of the hospital A new light department had been opened, and before long a new ear, nose, and throat department would be at work, thus relieving the present severe congestion in the out-patient department The Leopold ward would be set free by the coming into existence of the new ante-natal clinic There had been numerous unexpected benefactions during the year, including gifts by Lady Houston and Sir William Morris, but there was still a debt of £120,000 to keep them actively at work in the task of securing new financial assistance Professor Dudgeon said that the school was in a very satisfactory position as regards the number of students on the rolls, and the high standard which was consistently maintained He referred particularly to the loss the Medical School had sustained by the retirement of Dr A E Russell, senior physician to the hospital, and mentioned other vacancies which had occurred owing to appointments elsewhere obtained by members of the staff He commented on the way the difficulty in connexion with the directorate of the surgical unit had been triumphantly overcome, and breathed a spirit of cheery optimism as regards the future The toast of "Our Guests" was proposed by Mr Cyril Nitch, surgeon to the hospital, who enumerated the chief guests with appropriate comments Lord Riddell replied in a characteristically humorous speech, emphasizing how good the present times might be considered, when contrasted with the experiences of the past He warmly commended St Thomas's Hospital for the excellent work it was performing, and introduced a few reference or two to the Royal Free Hospital

MIDDLESEX HOSPITAL.

PRIZE DISTRIBUTION

The ninety-sixth winter session of the Middlesex Hospital Medical School opened on October 1st, when prizes and medals were distributed by the Minister of Health, Mr Arthur Greenwood, in the Queen's Hall, Langham Place Mr Samuel A Courtauld, the new chairman of the school council, presided, and the introductory address was given by Mr Eric L Pearce Gould, M Ch, F R C S

In contrasting the present state of affairs at the Middlesex Hospital with conditions thirty-four years ago, when he first knew it, Mr Pearce Gould recalled the changes that had taken place in the school and its associated buildings The old museum had been replaced by the Bland-Sutton Institute of Pathology, a new department of biology had risen above the reconstructed department of physiology, and across the street stood the Courtauld Institute of Biochemistry The whole of the hospital fabric, except the chapel, had been built since 1896, and with these changes of structure there had been changes of function Not only had the volume of work increased greatly, but there had been a profound alteration in the character of the services available for patients To-day all the special departments were staffed by specialists, with their own beds as well as out-patient facilities, while additional departments for special methods of treatment had been organized The changes that had taken place suggested that the progress of medical science had not been as slow as was supposed by some who looked askance at the ever-increasing expenditure and financial demands of the hospitals Nevertheless, the effort to take full advantage of these advances must strain the resources of even the best-endowed school or the best-supported hospital

Dr T Izod Bennett, dean of the Medical School, in presenting his report for the year, took occasion to remark on some of the defects in the education of the average English schoolboy who was proposing to become a medical student Neither in classics nor in science were public school masters providing an adequate groundwork for the study of medicine Under the present regulations of the University of London the first examination in chemistry, physics, and biology might be taken from school, but, although many students did so, the experience of teachers

at the Middlesex Hospital was that the standard of knowledge of these first year students was inferior to that reached by those who began to study the preliminary sciences in their own medical school

Annual Dinner

The annual dinner of past and present students was held in the evening of the same day at the Savoy Hotel, under the chairmanship of Dr C J Lakin, physician to the hospital In proposing the toast of "Prosperity to the Middlesex Hospital and Medical School," the chairman expressed regret at the absence of Prince Arthur of Connaught who was presiding that evening over the Guildhall banquet to overseas Premiers He said that the reconstruction of the hospital was going forward very well indeed More than two-thirds of the building programme was finished and paid for, two-thirds of the £1 100,000 asked for having already been collected When this great scheme was completed they would have a modern hospital of nearly 700 beds More than a quarter of a million was still needed to pay for the last section, but he did not doubt that it would be forthcoming The toast was responded to by Mr S A Courtauld Dr Ivon Bennett, and Mr P B Ascroft (Senior Broderip Scholar) Mr Courtauld said that this year marked the turning point in the reconstruction of the hospital He paid a warm tribute to the staffs of the hospital and Medical School and to Mr S G Asher his predecessor in the chairmanship of the school council In proposing the health of the guests, Mr W Sampson Handley paid compliments to the distinguished people who were with them that evening, and remarked that the Middlesex with its ideals of friendship, was fortunate in its friends Mr R J Meller, M P, responded on behalf of the guests, and Dr Henry MacCormac proposed the health of the chairman in a speech as witty as it was cordial

WESTMINSTER HOSPITAL

ANNUAL DINNER

The annual dinner of past and present students of Westminster Hospital was held at Grosvenor House Park Lane on October 1st under the presidency of Dr S Ernest Dore In proposing the toast of The School and the Students the chairman remarked that the Medical School which was beginning its ninety seventh year continued to maintain its traditions as an integral part of the hospital Progress had been shown in every department during the year especially in work on radium and disseminated sclerosis Last year twenty-six students entered the hospital A notable event had been the acceptance of the chairmanship of the School of Medicine Committee by Sir Henry Hadow on his retirement from the vice-chancellorship of Sheffield University Among other matters which the dean, Dr A S Woodwark, had referred to at the inaugural meeting earlier in the day, was a gift of £5 000, which had greatly assisted the development of the children's department, so that the hospital now afforded exceptional opportunities for the study of the diseases of children Distinction had also been won in the athletic field, for the record of the Sports Union was superior to any since the war, and included the winning of the junior association hospitals cup The toast was responded to by Dr Cecil Barlow and Mr N Heath the former giving some personal reminiscences of several members of the present staff nine of whom he was gratified to note, were old Westminster students Dr Adolphe Abrahams proposed the toast of "The Visitors," which was replied to by the Rev J Scott Lidgett, D.D, Vice-Chancellor of the University of London, and by Colonel Bulkeley An enjoyable evening concluded with the toast of The Chairman which was submitted by Mr Arthur Evans

An account of Dr Scott Lidgett's inaugural address was given in the *British Medical Journal* of October 4th (p 574)

THE MEAT-PREPARING INDUSTRY IN SOUTH AMERICA

[From a Correspondent]

A recent visit to South America afforded the opportunity for a critical inspection of the "*frigorifico*"—those huge establishments which daily convert thousands of cattle into meat for human consumption Having regard to the fact that nearly half the total amount of beef eaten in the British Isles comes from that remote region the subject is not without medical importance, so far as the purity of supply is concerned

When South America first began to utilize the vast herds of cattle which roved over its prairies it was in the form of jerked (*charqui*) beef This was made by cutting meat from the bone and stacking it in layers of salt. Prepared in this way beef retained its nutritive qualities for a long time, but it was a tough blackened product, and unattractive to ordinary civilized palates Then the canning process appeared, but has been superseded largely, first by frozen and later, by chilled beef The trade in these two last forms of food is of comparatively recent growth and sprang from several factors which arose almost contemporaneously Shipping lines pioneered by the Royal Mail Steam Packet Company installed refrigerating machinery great abattoir companies spread southward, and stock raisers were quick to appreciate the necessity for supplying the best cattle they could produce. Bulls were purchased from England without any stint of price and they soon transmitted their qualities to the South American stock The supply reacted to the demand created by successful transport and the trade is now in such a state that beef can be brought from La Plata 6,232 miles away at an inclusive charge of 9/16d per lb (less than the cost of rail freight from Glasgow to London) in a condition that makes it practically indistinguishable from home-killed produce

Organization of the Industry

Since by far the greater proportion of the meat supply comes from Argentina I will deal principally with that country Its economic heart lies in the Pampean division an area that spreads out like a fan four hundred miles from Buenos Aires and is devoted to cattle raising and cereals Vast though the pampas are covered by virgin pastures of rich nourishing grass here and there improved by intensive culture the country is regarded as fully stocked by cattle A conservative estimate has put the total at over forty million head of chiefly shorthorn Hereford and Aberdeen Angus types In 1925 a shorthorn bull was bought in England for £13,500 and since prices of £4 000 and £5 000 have often been paid for British bulls it will be seen that South American stock raisers are alive to the manner of obtaining the best produce The alfalfa grass which is a herbaceous plant belonging to the clover family is a most important factor as a source of nourishment In Argentina there are 14,000,000 acres devoted exclusively to it and crops can be cut six times a year, the grass being full of highly nutritious small kidney shaped seeds Before its introduction and the promotion of irrigation there were large areas of arid desert, which are now fertile plain Alfalfa pastures have wonderful muscle-producing qualities as compared with maize, which is more of a fattening agent The grass of the pampas and the alfalfa combine to form sturdy firm and well-covered animal which are entirely suitable for the meat market Practically the entire system of rail communication is British-owned and managed The country is well served by lines which extend to remote districts and facilitate the transport of cattle from the *estancias* direct to the *frigorificos* The transport is well managed the cattle come in orderly packed rows twelve to each covered truck There is not room for them to stand about at different angles and so be able to fall out to kick and gore each other On arrival at the *frigorificos* they are allowed to rest for twenty four hours at the end of that time they are herded towards a gangway up which they pass singly in a continuous stream to the knocking pen

The operation of killing is quick and merciful a skilled man wields a hedge-hammer which crushes the skull and renders the animal instantly unconscious It is then shackled on the

hind feet, and hoisted to an overhead rail The rail wheel takes them in front of the "stickers," who with deft, unerring aim drive a long thin knife down the carotid artery to the heart A pause follows, during which the animal is bled for ten minutes About four kilos of dried blood result, this is used for fertilizing purposes, and in some frigorificos for blood sausages If the animal was insufficiently bled coagulation would occur in the carcass The heads are then removed and the animal is skilfully skinned and sawn into four quarters In each frigorifico visited there was a plentiful supply of water, and a remarkably high standard of cleanliness was maintained throughout the whole process In this washed and clean condition the fore and hind quarters pass to the packing houses, where the meat undergoes freezing or chilling, after which each piece is wrapped in stockinette and again in Hessian cloth, and is then ready for shipment

Freezing and Chilling

Though it was by frozen beef that the trade sprang up, a great impetus was given by the introduction of chilled beef By the former process beef arrived in a hard condition and, unless carefully prepared for cooking, much of the albuminous juices drained away in process of thawing It is, however, as wholesome as chilled or fresh beef, and is not subject to rapid deterioration, it is usually sold at a lower price Chilled beef on arrival in England is scarcely distinguishable from the fresh article It is carried in steamers in which a steady temperature of 28° F is maintained in the holds, as against 17° F, which is the degree of coldness required for frozen beef The chilling process needs more prompt and careful subsequent handling than if the meat is frozen, it must be shipped within one week from the time the animal has been dressed, or it will deteriorate Freedom from the inclusion of any diseased meat is ensured by the companies' staff and by Government veterinary surgeons, who inspect the tongue glands of all the meat at an early stage of the proceedings They reject on an average 0 5 per cent of the carcasses, tuberculosis, fever, and anthrax being the chief causes Condemned carcasses are sent forthwith to a crematorium

Canning and Extraction

For canning, only beef with a low fat content (15 to 20 per cent) is used, since any other kind would require considerable skimming of fat The whole process of canning is most interesting, on seeing it one is able to understand how these tins of 'bully beef" maintain their contents in such safe and fresh condition for indefinite periods The meat in them is cooked and pickled, it is then packed into tins which are placed in a vacuum Air is drawn out through a small vent hole in the cap, and this vent hole is immediately sealed and soldered by an electric iron The cans are then stored in an incubating chamber for seven days, by this process unless the tins have been sealed in a perfect vacuum any such defect immediately shows itself Ingenious machinery performs the greater part of the work and the meat is scarcely touched by human hands Only those workers who have passed strict medical examination are employed, each one has to wear clean white overalls and have his hands inspected and manicured, both on entering and leaving the factory

In the preparation of beef extract only first-quality beef is used The meat is cut up, and all tendons are removed, it is then minced, and subjected to boiling After settling, the soup is skimmed to remove the fat It next undergoes filtration, and is evaporated to 25 Beaume scale in open aerating pans, it now contains not more than 16 per cent moisture This is the pure beef extract, and the whole process takes five days To make 10 lb weight of this extract 100 lb of beef are required No chemicals or any other matter are added, the salt taste is nothing but the salt contained in the flesh

Some mention should be made of the by products from the meat supply Glands such as the thyroid, pancreas, and ovaries are extracted, treated, and dried they are then shipped to England in zinc lined cases Gall stones are sent to Japan, where they are used in the preparations of dyes Brains are cleaned and chilled, they are then packed for export for consumption Livers are dealt with in the same way Lungs and spleens are made into meat meal, which is used as animal food and fertilizer, tendons and the male organs are dried and sold for glue stock Hides are pickled in brine, and then piled in layers with a covering of salt Bones are trimmed, defatted, cooked, washed, and dried, they are then exported for use in making buttons, knife handles, etc Intestines are prepared for use as sausage casings

Output of the Frigorificos

More than half the meat sold in Smithfield Market comes from South America, and about one third of all the meat consumed in Great Britain As nearly as can be ascertained South America supplies three quarters of the world's total export The last official returns from Argentina show that 428,798 tons of chilled beef and 63,954 tons of frozen beef were exported during the previous year Including also Uruguay and Brazil, the total output for 1928 was 646,437 tons of beef It has been estimated that there are 68,500,000 head of cattle in these three countries alone, and this does not take into account the millions of sheep which are also raised From these figures the enormous extent of the trade can be judged, and when consideration is paid to the clean and careful methods of production and transport there is every reason for satisfaction with the purity of our imported meat supply In Argentina and Uruguay the Governments are alive to the importance of the trade, and to its maintenance in as perfect a state as possible They therefore supply to each frigorifico a staff of official veterinary inspectors, who are independent of the companies and who closely examine every carcass in its progress through the factories

Sheep and pigs are handled in much the same way The heavy odour of sheep skins is minimized by the rapid transport of the fleeces to large, airy sheds, where they are washed and treated with chemicals to make the wool easily removable The wool is then carded and baled, and the skins are sorted for export The carcasses, after being gutted and washed clean, pass on to the chilling chambers, they are there sewn up in Hessian cloth and pass on an endless chain straight into the cold holds of the steamer drawn up alongside. All this is done with remarkably little handling Steamers carry refrigerating engineer officers, who are specialists in maintaining appropriate temperatures throughout the voyage

Correspondence.

PERFORATING DUODENAL AND GASTRIC ULCERS

SIR,—With your permission I would like to thank your several correspondents for their friendly criticism of my paper on acute perforating duodenal and gastric ulcers, which was published in the *Journal* of August 2nd (p 169) It is obvious that there are many points with regard to the pathology, symptomatology, and treatment in which there are certain differences of opinion among the profession, but most of these, I think, will be capable of a satisfactory adjustment in time

Mr Harold Dodd thinks my idea of the mortality not exceeding 5 per cent is a counsel of perfection, it may be so, but, taking the figures for acute perforative appendicitis, a 5 per cent mortality is not thought anything wonderful by many surgeons, and personally I consider it a more dangerous lesion In my opinion the predominant factors in success will always depend upon early diagnosis, early operation, perfectly planned anæsthesia, and meticulous after-treatment

I wish to offer my sincere apologies to Professor Grey Turner for any disservice I may have done him by quoting figures that did not strictly refer to operations performed, which in his case should be 15 64 I hope, therefore, to publish a more correct table at an early date, with explanatory notes I would also like to congratulate Mr Basil Hughes on his excellent results At the same time I may state here that in an experience of these cases during the last twenty-five years I have never met a single instance of shock in an early case, and I have seen a number within one and two hours after perforation I have always operated as soon as possible, and am in absolute agreement with Dr R O Adamson on this point

Further, I may state that in my table, which was referred to by Professor Grey Turner and Mr Basil Hughes, some of the earlier results given include operated and non-operated cases and perforating malignant ulcers I would

like to emphasize the time element in the earlier figures Taking Sir Percy Sargent's cases in 1904, the average time that had elapsed between perforation and operation in the successful cases was 23 hours, and in the fatal cases 22 6 hours, whereas to-day it is very seldom that I see a case that has been perforated longer than 12 hours, in fact, my own earlier experience was of late cases as a rule, when subphrenic abscesses were far from uncommon The late H L Barnard in 1908 published a series of seventy-six cases of subphrenic abscess, and found that of these twenty-seven were secondary to perforating ulcers of the stomach and duodenum Finally, I want to thank Mr Russell Coombe, and Drs Holden and Adamson, for their interesting additions to the historical side—I am, etc ,

JOHN H WATSON, M B , B S , F R C S

Barnley Sept. 30th.

SIR,—Surely to-day we have a very different conception of shock from what obtained in the nineties Such is one of the really valuable heritages of the late war, which taught us much and gave us a new outlook upon the treatment of perforations of viscera I do not wish to refer to the terrible operative mortality of abdominal injuries earlier in the war, when hypodermic morphine and immediate operation under ether narcosis, as still approved by Dr Adamson, was practised, but I do wish to emphasize the later results in which the mortality was reversed when the value of resuscitative measures primarily, and the extraordinary benefit of gas and oxygen anaesthesia were recognized and put into effect by some of our leading anaesthetists Such a lesson must be a lasting one to those of us who were overseas It is the application of this lesson to civil surgery which has granted in my own cases of perforating gastric and duodenal ulcer a mortality of 12 per cent The choice of spinal anaesthesia over gas and oxygen anaesthesia may be selfish They are both non-toxic, but spinal anaesthesia makes the surgeon's task both easier and quicker The fundamental surgical principles, however, still remain for such cases—namely that in perforations of any abdominal viscera "Don't operate on a falling blood pressure, for this is inviting disaster Employ resuscitative measures first, wait for the rising blood pressure, and then operate"

With reference to Dr Adamson's remarks upon cigarette smoking and its connexion with hyperacidity and ulcer, I would refer him to the very convincing work of Lord Moynihan on this subject—I am, etc ,

BASIL HUGHES, M B , B Sc , F R C S

Bradford Oct 6th.

INDICATIONS FOR PERFORMING WILDE'S INCISION

SIR,—An article by Mr T B Layton under this heading in the current number of the *Journal of Laryngology and Otology* raises a question of such importance that a further expression of opinion by otologists and all those interested in the aural complications of infectious diseases seems called for Mr Layton, whose opinion necessarily carries weight because of his long experience with the Metropolitan Asylums Board, asserts that "in all cases of infectious disease in which retro-auricular swelling arises, it is best to make a Wilde's incision" This is a very sweeping and very surprising statement, the two exceptions quoted—namely, rigidity of the neck and the presence of rigors—do not materially alter the general proposition

I suggest that there are four causes of retro-auricular swelling occurring in the course of infectious disease (1) furunculosis, (2) adenitis (3) pus tracking from the middle ear along the bony meatus without bone disease, and (4) mastoid disease with or without further complications It is surely the aural surgeon's duty to try to see the which condition is present and then to use the appropriate treatment, but not to rely on a stereotyped panacea In (1) and (2) a superficial incision is all that is necessary, in (3) a Wilde's incision is appropriate and is performed by most aural surgeons In my experience however, such cases are rare in children over the age of 5 years, and distinctly less common than true mastoid disease, even in those below this age In (4) a complete mastoid operation is preferable, because one operation is better than two It is admitted by Mr Layton that where the mastoid is diseased Wilde's incision will not be sufficient to effect a cure, and a further operation will be necessary

In the comparatively uncommon cases when the patients are desperately ill, one would be content with a very rapid opening up of the antrum and cells, taking care to make certain that no extra dural collection of pus is missed This can be done very rapidly, and with a properly given anaesthetic entails a minimum of risk In these severe cases it is the exception rather than the rule to find pus under the periosteum a more incision down to the bone would therefore be of little use Such cases in which an incomplete operation is performed, are certainly slower to heal than those in which all diseased bone is removed they may require a second operation, or may heal after extrusion of small sequestra

It is further suggested that Wilde's incision may sometimes be useful in infants "in cases in which the swelling is in front of the ear" If this is to be understood as referring to cases with swelling both over the mastoid and in front of the ear, the foregoing remarks apply If there are cases in which pus tracks along the anterior wall of the meatus alone, without bony involvement it is difficult to see how a Wilde's incision would help

Mr Layton gives as a reason for Wilde's procedure that the condition of patients suffering from diphtheria scarlet fever, and measles contraindicates the administration of a general anaesthetic, so I conclude that he uses either a local anaesthetic, as he does in adults, or operates without anaesthesia Most surgeons have found local anaesthesia quite impracticable in small children, and most will be against operating without an anaesthetic except in very superficial abscesses

After considering the points in detail we must conclude that the only advantage of a routine Wilde's incision is to enable a house-surgeon, untrained in ear work, to deal with all retro-auricular swellings by a routine method This used to be the practice in many fever hospitals, and still continues in some, but it cannot be seriously defended I am not surprised that Mr Layton was "unable to find any textbook to-day which speaks favourably of this operation"—I am, etc ,

E S BURT HAMILTON, M.B. F.R.C.S.Ed., Consulting Aural Surgeon, Manchester Fever Hospital

September 28 th.

PYREXIA OF UNCERTAIN ORIGIN

SIR—Dr Hotson Palmer's letter on this subject in the *Journal* of September 27th (p 543), although but a thumb-nail sketch, is a valuable contribution to the literature of influenzoid conditions Such local pyrexial epidemics presenting unusual features are not uncommon, yet their occurrence is seldom recorded—as I learned to my cost when I searched the *Index Medicus* for some light upon the following sequence of events

At 6 p m on September 28th, 1927, I saw a boy in a public school infirmary who was markedly prostrated, breathing in short, sharp jerks, and complaining of intense pain in the upper part of the abdomen His epigastrium was rigid like a board, his temperature was 101° F , and the chest was clear I anticipated increased surgical activity within a few hours, but before 10 p m had admitted four very similar cases, a coincidence which took my mind off surgical matters Next morning twenty boys were ill, and within a week sixty cases had occurred Pyrexia, a mild nasopharyngitis, and girdle pains were fairly constant The pains picked out two or three spinal segments, and were more commonly unilateral Tenderness, cutaneous hyperaesthesia, and some disturbance of the tache, were frequently noticed along the painful segments, of which the mid-dorsal were most commonly involved, giving rise to rapid and very painful breathing In the lower dorsal and upper lumbar regions there were signs mimicking the "acute abdomen" and I feel certain that had two or three of the cases occurred outside the epidemic, exploratory operation would have been performed—particularly on one boy with marked rectal

tenderness The upper dorsal segments were concerned in comparatively few cases, but pain in the neck on movement was not uncommon, and gave rise to guarding There were, however, three patients in whom the neck rigidity was associated with Kernig's sign My notes on two of them may be of interest, and I suggest that they were similar to the cases seen by Dr Palmer

Case 1

C E, aged 13, on the morning of October 2nd had a temperature of 99° F, his pulse rate being 84 There was shallow and painful respiration, with violent frontal headache, and the right side of the chest was moving badly Pains were felt all over the body on movement, mainly in the right epigastrium, which was tender The right iliac fossa was also tender and guarded In the afternoon the temperature was 100 8°, and the pulse 84 The abdomen was less rigid, but the headache worse

On the morning of October 3rd the temperature was 99° and the pulse 70 There was epistaxis, and an increase in the tache cerebrale on the right side of the trunk Some pain remained in the right epigastrium and chest, the headache was unaltered In the afternoon the temperature was the same, but the pulse had risen to 88 Headache was caused by movement, and the tache was now very bright when the right hypogastrium was stroked

On October 4th the temperature and pulse had become normal and the headache had improved, but the patient now complained of a sore throat In the afternoon the temperature was 99°, and there was tenderness over the third to the sixth costal cartilages on the right side movement was difficult

On October 5th the temperature had returned to normal, the headache was much less, and there was general improvement The next day the patient was fairly well, except for tenderness at the tip of the tenth rib on the right side

In the afternoon of October 7th the temperature had risen to 101 4°, the pulse being 56 Intense vertical headache, increasing, was associated with nausea, pain in the eyes, and tightness of the neck At 7 p m the patient vomited and the neck was very rigid, attempts at flexion producing great pain along the costal margin A definite Kernig's sign was present, but the reflexes were normal The next day he was exhausted but much more supple and rapid recovery ensued

Case 2

T, aged 12, on October 6th complained of abdominal pain during the morning He vomited about 4 p m, before admission The temperature was 99 4°, and the pulse 100 and feeble There was temporal pain on the right side, this had been bilateral earlier in the day

On the morning of October 7th the temperature was 100 6° and the pulse rate 100 The patient had vomited frequently during the night and complained of pain a little above the umbilicus and over the right temple The neck was rigid, and a definite Kernig's sign was obtained Ankle jerks were absent, but the knee jerks were brisk There was an extensor plantar reflex on the left side and nystagmoid movements of the eyes to the right

In the afternoon of October 8th the temperature was 99 6° and the pulse 96 The patient was becoming increasingly restless, twitching and picking movements of the arms and hands being noticeable there was slight epigastric pain but very little headache and diminished neck rigidity Kernig's sign was unaltered Reflexes of the left leg were less brisk than those of the right, and the nystagmoid movements were now to the left

On October 9th there was a slight increase in the stiffness of the neck Kernig's sign was still present, and the reflexes were feeble on the left side The temperature and pulse returned to normal and the boy was up and about in ten days, but at the end of this period his legs were still "guarded" on flexion of the hips

I am satisfied that the signs of meningeal irritation in these cases which looked serious for a few hours, were "faked" by the guarding of painful spinal segments No zoster occurred, but one boy produced dermatographia over his painful region

This epidemic of "intercostal neuralgia" had an influenza-like "steeple" incidence curve the nasopharynx was I take it, the portal of entry of an unknown neurotropic virus Coryzas and mild sore throats without systemic disturbance were increased at the time, but did not resemble clinical "influenza" The "influenza" bacillus and meningococcus were not present in the flora of the community at the time I believe parts of London and the south-east coast were visited by a similar epidemic in October 1927.—I am, etc,

W H Bradley, B M, B Ch Oxon.

Stratton on-the-Fosse near Bath Sept 30th.

Sir,—In reference to Dr Hotson Palmer's letter I would suggest that his cases may be classified as acute benign serous meningitis The summary of cases reported by Andersen and Wulff (*Epitome*, September 13th, para 225) would furnish confirmatory evidence

I am of opinion, particularly in view of a recent personal experience of one case in which after an attack of serous meningitis in August, 1929, typical encephalitis followed in April, 1930, that these cases of his should be carefully observed during the next six to twelve months at least for signs of either chronic encephalitis or—the more probable development—the onset of acute encephalitis (so called "lethargica") If Dr Hotson Palmer so desires I shall be glad to furnish him directly with the details of this case

As to Dr F P Halkyard's sign, while the number of pure meningitis cases I have seen is relatively small, it has been my constant experience during the past five years that this sign is present in all cases of encephalitis, even when definite neck rigidity is not present I have even seen cases in which the pain was referred to the lumbar region on neck flexion I have never found the Brudzinski sign (of which this is, so to speak, the first stage) present in encephalitis Andersen and Wulff report it, however, in their serous meningitis cases Those observers have noted an affinity between serous meningitis and epidemic encephalitis, a point which I believe deserves more attention and research, in view of the constant though not always obvious presence of meningitis in cases of the latter disease.—I am, etc,

Dublin, Sept 30th Morgan D Kavanagh, M B, B Ch

Sir,—May I state that cases resembling those described by Dr Palmer are by no means infrequent here, there have been a considerable number during the past five years, many of which have occurred during the summer or early autumn months The chief symptoms are fever, headache, and neck rigidity, with positive or doubtful Kernig's sign, and there may be transient photophobia, squint, or alteration in the reflexes The illness is of variable duration, lasting from three days up to several weeks, and relapses may occur The symptoms usually disappear with remarkable suddenness The majority of the patients recover completely in the absence of complications

The cerebro-spinal fluid is under increased tension, and in the early stages contains an excess of cells, mainly polymorphonuclear and large mononuclear cells, as recovery takes place the cells disappear from the fluid with striking rapidity, and I have seen a fluid definitely purulent on one day show only a slight increase on the following day, and be without cell increase a couple of days later On careful search of Gram-stained films organisms may be found, frequently in small clusters and only after prolonged search, they are Gram-negative, and are varieties of a pleomorphic organism, occurring in the form of short bacilli, diplobacilli or short filaments On culture we have repeatedly obtained a Gram-negative bacillus, with cultural characteristics resembling those of *B faecalis alkaligenes* and from it, as from some of the cerebro-spinal fluids, we have obtained a stable filamentous variant

Dr Ivy McKenzie whom I have assisted in the investigation of these cases, described them under the name of "leptothricosis" or "leptothrix meningitis" some years ago (*Glasgow Medical Journal*, October, 1926), and some of the characteristics of the organism were described last year (*Supplement*, 1929, vol ii, p 148) in the report of my investigations carried out in connexion with a B M A research scholarship.—I am, etc,

Glasgow, Oct 4th Albert A Fitzgerald Pepi, D M

THE BLOOD CALCIUM IN DIABETIC RETINITIS

Sir,—In my paper on diabetic retinitis (*Proc Roy Soc Med*, 1930, xxiii, 292), which is criticized by Dr R D Lawrence and his fellow workers in your issue of October 4th (p 559), I emphasized the fact that in my opinion the changes interfering with visual perception and the haemorrhagic tendency found in some cases are of independent origin, the former being probably due to local

disturbances induced by the diabetic state, whereas the latter is partly dependent upon a deficiency of calcium in the blood arising from metabolic changes which are not a direct result of the diabetes, and I pointed out that, while the tendency to haemorrhage is quite uninfluenced by insulin and ordinary dietetic treatment, a simple diabetic retinitis quickly responds to such treatment I fail, therefore to understand their statement that I have claimed a calcium deficiency as the cause of diabetic retinitis The fact that they found a "normal" blood calcium in ten unselected cases of diabetic retinitis has no bearing on the main point of my paper, which was to show that where there are retinal haemorrhages a low blood calcium is a characteristic feature, and that the haemorrhages can be prevented by the administration of calcium unless their series included examples of this particular type

If Dr Lawrence and his associates will refer to the original authorities they will find that Kramer and Tisdall (*Journ Biol Chem*, 1921, xlvii, 223, *Bull Johns Hopkins Hosp*, 1921, xxxii, 44) give 5 5 to 6 8 mg per c nt of calcium as the limits for normal whole blood, and 9 5 to 10 5 mg per cent for serum On these figures one, and possibly more, of the cases they quote had actually a serum calcium below the limit regarded as normal by the inventors of the method of estimation they employed In my own work I have found it more convenient to use whole blood, and as I have referred to the "blood" calcium or the "fasting whole blood" calcium throughout my paper it would hardly seem necessary for them to suppose whole blood was "presumably" meant, although the fact that they do so is interesting psychologically — I am, etc,

London W 1, Oct. 6th. P J CAMMIDGE

INTRAMUSCULAR AND INTRAVENOUS QUININE

SIR,—Being a medical practitioner in Uganda, where malaria is very common, I was much interested to read Major Biggam's remarks about intramuscular administration of quinine in the *British Medical Journal* of June 28th (p 1171)

Damage to the sciatic nerve does occur if the injection is given in the gluteal fold, but it can be easily avoided Tetanus is also feared on account of muscle fibre necrosis, but it is very rare I have given hundreds of intramuscular injections of quinine, and my colleagues in Uganda have perhaps given thousands, but no case of tetanus has so far been reported

As regards local pain, my experience is quite different I have given almost painless injections of quinine intramuscularly Pain cannot be produced if the solution is injected in the muscle, as it is generally due to a few drops of the highly concentrated quinine bihydrochloride solution entering the skin and subcutaneous tissues I am always careful to prevent a track of quinine solution forming in the skin and subcutaneous tissues by washing my needle in plain boiled water after sucking the solution from the ampoule I also empty the needle of the solution by sucking air into it before giving the injection (or preferably two needles may be sterilized, and one used for drawing the solution into the syringe and the other used for injecting) Further, after injecting the solution in the outer and upper quadrant, I keep the needle in the muscle, detach the syringe and suck air into one barrel, and inject a few bubbles of air into the needle to empty it completely of the irritating solution The idea is to prevent another track of quinine solution forming in the skin on withdrawing the needle I think if this simple precaution is taken, a painless quinine injection can be given

Despite these points in favour of intramuscular administration of quinine, I personally prefer the intravenous route, particularly in view of the "fixation abscesses" recently reported by Giglioli which I think are a real danger Intravenous injection is painless more rapid in action, and its use is indispensable in cerebral and subtertian cases with persistent vomiting and diarrhoea I hope my colleagues will give this method a more liberal trial in East Africa I personally use one ampoule (0 6 gram) Burroughs Wellcome and Co, diluted with 10 c cm of distilled water, and inject very slowly — I am, etc,

M S NAWAZ AHMADI, M B, B S

Mulindi Uganda, Aug 13th

ACTION OF QUININE ON THE UTERUS

SIR,—Until our obstetric teachers will endeavour to explain their contradictory statements, ordinary practitioners must continue to follow their own opinions (or alternatively, suffer headaches from antagonistic complexes!)

On the one hand I read[1] that quinine is an essential as a stimulant to the uterus in Gwathmey's system of analgesia built on a trial of 20 000 cases 'If the quinine is omitted, the method is a failure" He gives the quinine into the colon and tests the urine to be sure it has been absorbed Turning next to page 89 of the current volume of the *British Medical Journal*, I read that Drs Bourne and Burn find that quinine "has very little effect of a kind calculated to hasten delivery" I note incidentally that they give the quinine into the muscle (a route notoriously to be employed when slow absorption is desired) and made no test apparently to ascertain if the drug had been absorbed at the time the test record was made

Dr Bourne very possibly is right—very probably is so—but if I were on a jury and had to give my verdict after hearing the above two opposing statements, I would say that the American had made out a better case—at least one that prima facie was definitely more convincing to the ordinary medical man who does not care who is telling the truth, just so he is told the truth I contend that to publish such a report of the action of quinine in two cases is most unsatisfactory, it may be true, but it does not begin to *appear* to be true

Of course, in the words of the song, "I'm always wrong, so how can I tell?" Yet how many hundreds of practitioners are anxious to learn, once and for all, what effect the common drugs have on the parturient uterus? Dr Bourne's paper is a most valuable one, and my criticism is directed only to one section of it. That section should be substantiated or demolished as soon as possible for as it stands it is unworthy of the rest of the report —I am, etc,

Hankow Sept. 11th. A H SKINNER

PERSONNEL OF A RADIUM CLINIC

SIR,—Without wishing to prolong a discussion about which some people evidently feel strongly, I should like to reply to Dr Stanley Melville when he says, "That the radiologist was to be excluded from taking his proper place in the future administration of radium was all too evident until Scotland showed us the way"

I cannot think there is or was any conspiracy to exclude such a useful body of investigators, engaged in a science which is comparatively new and therefore experimental but which has added to medical science some of its most brilliant advances during the short time it has been in existence I do not think that there is any responsible radium institute conducting original research, ready to teach all comers and willing to employ investigators—in fact, to do all the things which a modern radium institute must do on such a new subject as radium—which has attempted to eliminate the proper use of radiological investigation The three large centres in Europe—Paris, Brussels, and Stockholm—certainly never have nor have the smaller and less known centres in Germany I exclude institutions where radium was hired to anyone indiscriminately and which were purely money making concerns, but then these institutions are hardly likely to dictate to the position of any respectable body of workers At the Mount Vernon Hospital which we hope will be the main centre of cancer research in this country, the very latest

[1] Gwathmey *Surg., Gynec. and Obst.*, August 1930, p 151.

radiological apparatus is being installed, and the best investigators are being appointed

So far the results of x-ray work in the treatment of cancer have been disappointing to surgeons, considering the way their advent was hailed by even responsible radiologists, nor as yet have the centres I have already mentioned reported any great advance in the way of results, hence the search for higher voltage, more powerful installations The future of x rays in the treatment of cancer is as yet comparatively unknown in spite of the utmost work bestowed upon it But if it should be found that these rays have the effect we hope they have upon deep seated growths on which radium can hardly be expected to be of use, and the two related wavelengths prove to be complementary to each other, a position they do not hold to-day, we shall have a pair of weapons for surpassing the use of the knife Before this can be established an enormous amount of investigation is required, and it is imperative that we have the services of the ablest radiologists available Dr Stanley Melville can rest assured that this is the opinion of every far thinking radium investigator throughout the country I am, etc,

London W 1 Oct 6th DUNCAN C L FITZWILLIAMS

Obituary

C POWELL WHITE, M D, F R C S,

Late Special Lecturer in Pathology, Manchester University

Dr CHARLES POWELL WHITE who died on September 26th, was the fourth son of the Rev L Borrett White, D D, Canon and Prebendary of St Paul's, and Rector of St Mary Aldermary, one of the City churches He was one of a large family, members of which are in the Church or in the teaching profession Incidentally it may be said here that White always retained a great interest in the Established Church and his last publication was a letter to the press in support of the revision of the Prayer Book

He was born in 1867, and was educated at St Paul's School, London, Sidney Sussex College, Cambridge, and St Bartholomew's Hospital He was an unusually able scholar winning many prizes and distinctions in his career At Cambridge he attained a high place in the mathematical tripos before entering on his scientific studies He became qualified in 1894 with the conjoint diploma of the London colleges and in 1896 took his Cambridge M B, B Ch degree and the F R C S In 1900 he proceeded to his M A and M D degrees By these surgical and medical achievements he showed that he had an unusually receptive mind, and one that could take a broad view of a professional subject In 1894–95 he held a research studentship in pathology He was pre-eminently a man of the academic type of scientific mind, with very wide interests, retiring in nature and without the needful push and energy to attain the highest posts, whether in practice or in directing a teaching school These mental characteristics were but a reflection of his physical powers, for even as a boy he could never run 100 yards at speed, and yet in more mature years he could walk all day long, over hill and dale, at his own meditative pace So, after serving as house-surgeon at St Bartholomew's, he threw in his lot with the scientific side of his profession and became assistant pathologist at St Thomas's Hospital About nine years were spent in this and subsequent pathological posts at the General Hospital, Birmingham, at the Yorkshire College, Leeds, and again, in a senior post, at St Thomas's Hospital

In 1906 he was appointed to the Pilkington Research Fellowship, which had recently been created in the University of Manchester through the interest of the late George Arthur Wright, and he also became attached to the Christie Cancer Hospital as unpaid assistant to the honorary pathologist In 1911 a new post of pathologist to the hospital, with special salary, was created for him As a special lecturer in pathology in the University he delivered lectures on cancer, some of which were published in 1908 He subsequently became director of the Helen Swindells Cancer Research Laboratories in the University and histologist to the Manchester Committee on Cancer It was in these Manchester posts that he became so widely known as an authority on pathology, and especially on the cancer question in all its phases He was an active member in the Council of the British Empire Cancer Campaign The papers which he published are too numerous to mention here In 1902 he delivered the Erasmus Wilson Lectures of the Royal College of Surgeons on the general pathology of tumours, which were a forecast of his work in 1913 on the "Pathology of growth" In the preface he claimed to have laid most stress on the physiological and biological aspects of the subject, and he had every reason to justify such a claim, for he had studied cytology with his extensive and sound knowledge of biology, physiology, chemistry, and physics, and a very thorough acquaintance with the philosophy of science as propounded by Huxley, Darwin, and others In 1927 he published *Principles of Pathology* In his preface he said that he had been accused of being too dogmatic in some of his previous statements If he had, it was not with the intention of laying down the law, but to attract notice to certain points, a positive or dogmatic statement arresting attention and provoking criticism, where a hesitating, non committal statement is apt to be passed over as of no account Powell White took an active part in forming within the British Medical Association a committee of pathologists of the kingdom to watch their interests, among other things in the matter of appointments and salaries Among the many posts and scientific honours of his life one which pleased him as much as any was that he was treasurer of the Pathological Society of Great Britain from its foundation, and the respect in which he was held by his fellows was shown by their handsome response to a call for financial help in his permanently incapacitated state He was very widely read in general literature, and his knowledge of natural history and the common objects of the roadside—plants, birds, butterflies, fossils—made him a delightful holiday companion for old and young

These inadequate and somewhat personal notes of a man who had so many friends outside the scientific world may be concluded by a happy memory of holiday walks with him along a certain favourite cliff on sunny days, with blues, small coppers, tortoise-shells, meadow browns, flitting about the banks whereon the wild thyme grew, and whereon lizards—anxious for their tails so easily left behind, and on which he had designs, for he wrote a paper on their regeneration—disported themselves, and on one occasion water-divining experiments with a medical friend and expert on it, in which we were joined by a local celebrity who subsequently proved to be better able to divine the needs of the country in time of stress than he then showed he was in divining water It was after a return from this favourite district two years ago that White was suddenly incapacitated and inflicted with a wearying and often very painful illness, which the sympathy of his many scientific and general friends helped him to bear with much fortitude He married in 1918 Jettice Mary, daughter of Horace Lamb, F R S, one-time professor of mathematics in the Manchester University, who survives him with a son and a daughter E M B

Dr JOHN O'DONNELL of Merrion Square, Dublin, who died on September 24th, was a brother of the late Cardinal O'Donnell, Archbishop of Armagh Born at Glenties, co Donegal, Dr O'Donnell was a distinguished student of the Catholic University Medical School, St Cecilia Street, Dublin, and graduated M B, B Ch, and B A O at the Royal University of Ireland in 1892 Though advised in early life to live abroad, he used to say that he would rather die in Ireland than live in another country Most of his professional life was spent in Dublin One of his first appointments was resident physician to the Mater Misericordiae Hospital, to which he subsequently became senior physician, a position he held till his death For many years he was medical officer to the Civil Service, to the Dublin Metropolitan Police, and to Kilmainham Prison On the foundation of the Tuberculosis Hospital at the Pigeon House he was appointed visiting physician, and acted for a period as consulting physician to the

Crooksling Sanatorium and to St Michael's Hospital Dun Laoghaire As an authority on lung diseases he published several contributions on this subject Dr O'Donnell had a lovable disposition, and his devotion to duty and the attention he gave to his patients won the respect and esteem of all who knew him He leaves a widow and five daughters, one being married to Dr Eugene Kelly, who practises in London

---

Dr Andrew Chillingworth, who died at Bedford on September 30th, aged 76, while making his usual morning round, received his medical education at St Bartholomew's Hospital, he obtained the diploma M R C S Eng in 1879, and the L R C P Ed and L M two years later After holding the post of house-surgeon at Salop Infirmary he went to Bedford forty-seven years ago, and entered into partnership with the late Dr J Carter Since January, 1921, his son, Dr A J Chillingworth, has been in partnership with him Dr Andrew Chillingworth was also medical officer to the Bedford Provident Dispensary and the Bishopstone House Asylum He was an ex president of the South Midland Branch of the British Medical Association, and also of the Bedford Medical Association For many years he had been churchwarden at St Peter's Church, Bedford, and took a prominent part in the work of this parish Always keenly interested in open air sport, he had been particularly proficient at cricket and Rugby football, and played golf until two years ago He leaves a widow and two sons, both of whom are in the medical profession

---

With the recent death of Dr Hugh Thomas Warnock, Invereske, Donegal, Ireland loses one of her most popular physicians He had been in ill-health for some time, and retired from practice in May of this year On graduation in 1876 he was appointed demonstrator of anatomy in Steevens's Hospital Dublin, having obtained the diploma I R C P I in the previous year Among the posts which he held during his active life were medical officer to the local district and fever hospital, and consulting surgeon to the Shell Hospital, Ballyshannon He became a Fellow of the Royal College of Surgeons in Ireland in 1889 Dr Warnock took a very prominent part in Irish medical politics being in 1928 both president of the Irish Medical Association and chairman of the Irish Committee of the British Medical Association, of which he was one of the oldest and most conscientious members Although his attendance at medical conferences in Dublin meant an absence of three days from his home and practice, he rarely missed a meeting His death is also widely regretted for his public service, especially among the poor, for whom he did much to provide up-to-date medical treatment

---

Dr Gertrude Grogan died suddenly on September 20th, while on holiday in Bavaria, and by her own wish she was buried at Tegernsee She was born at her father's rectory in county Wicklow, and attributed her facility in drawing to her father's habit of asking her to sketch from memory anything she had seen on her walks Later on she astonished one of her ambulance classes by drawing a skeleton from the feet upwards She received her medical education in Dublin, graduating M B , B Ch , B A O in 1895 For several years she was assistant medical officer at Mullingar Asylum, and later at Fulbourne Asylum Cambridge She then undertook general practice in North London, combining with this some part-time medical work in connexion with the General Post Office She was one of the pioneers in child welfare work and gave to it many years of voluntary service At the time of her death she was medical officer to infant welfare clinics in Brixton and St Pancras, and to the St Luke's Day Nursery, Holloway An ardent supporter of the St John Ambulance Association, she was divisional surgeon for Finsbury, and for about twenty years lectured at the Northampton Polytechnic Institute on first aid home nursing and hygiene She spared no trouble in preparing for these lectures and was always on the alert to find new illustrations and anything which could add interest to them She was a keen student of Esperanto and spent many holidays in attending congresses A colleague writes Dr Grogan was a most approachable person, with a great gift for setting people at their ease Her Irish wit and ready invention improved every story that came her way and she was physically incapable of being dull, however unpromising the subject She loved life and all its doings however small The mothers at the welfare clinic loved her for she was glad or sorry with them, but never impatient or hurried with them Whenever she had a pleasure her first thought was, "With whom can I share it?" Innumerable were the small kindnesses that she did

MOTOR CARS FOR 1931

THE OLYMPIA SHOW

[From our Motoring Correspondent]

For many years past the annual Motor Show at Olympia has been looked upon as one of the chief functions in London's autumn programme of events, the exhibition attracting visitors not only from every part of the United Kingdom but from all the principal countries of Europe, and even from those further afield The 1930 show, which will open its doors on Thursday next, October 16th, and continue until Saturday, October 25th, is the twenty-fourth of the series organized by the Society of Motor Manufacturers and Traders, and, judging from the advance information we have gleaned, there are every signs of it proving one of the most successful Certainly it will be the largest exhibition of the kind so far held in Great Britain, for the Motor Show of 1930 is not being confined to displays of chassis and cars, and to motor car accessories and components On this occasion two new sections are being added—one in which special devices for the servicing and maintenance of motor vehicles will be grouped together, while another part of the building will be devoted to motor boats

Hitherto the show has occupied what were known as the Main and New Halls and their respective galleries, but since last year the huge additions which have been made to the Olympia buildings have been completed, all of which are being brought into use for the coming exhibition Space only permits us briefly to mention that there will be approximately 74 firms showing cars, 54 separate displays

of vehicles with special bodywork by well-known coachbuilders, 15 different exhibits of tyres, over 300 of accessories, 67 of service garage equipment, and 54 of motor boats and allied goods. So far as the car section is concerned, its international character is indicated by the fact that the latest motor vehicles produced in no fewer than eight countries will be available for inspection. British car builders will be in the lead with thirty-two different makes, but France and American motor manufacturers will again be strongly represented.

The Trend of Design

With a few exceptions, such as a larger number of cars fitted with four-speed, silent third gearboxes, automatic and semi-automatic change-speed gears, the coming show does not promise to reveal any startling departure from what has become almost the standard layout of cars. At the same time manufacturers have all been devoting considerable attention to improving the details of their productions, and to rendering them more attractive to the motor-using public. Although four-cylinder cars by reason of the attractive prices at which they are now being offered and the good service they are rendering in actual work will long remain popular among those to whom the amount of first cost is of importance, the exhibition will reveal a further marked increase in the range of cars with engines having six or more cylinders. From the popular point of view, and also from that of a large proportion of medical men, interest will probably centre very largely in the examples of six-cylinder cars of about 15 h.p. which have been announced by several well-known manufacturers, and which in saloon form are being offered at prices ranging from £199 to £250, while in the £250-£300 category there are several well-known "sixes" which have been adopted with success by many medical motorists during the past year, as well as several interesting newcomers, such as the Vauxhall Cadet, which will undoubtedly repay examination. For those who can afford a little greater initial outlay and who desire the maximum smoothness of running, there is a growing number of eight-cylinder vehicles, some of which are now available at prices for which a few years ago only four-cylinder vehicles could be purchased.

Lower Car Prices

Indeed it may be said that the outstanding feature of the show will be that despite the fact that there is no slackening of endeavour to improve the efficiency and general reliability and comfortable riding qualities of cars, most of the manufacturers have seen their way to offer them at lower prices. In bodywork the saloon type continues far and away the most popular. Indeed, one old motorist was recently heard to remark that it would seem that contrary to the practice in the early days of the motoring movement the covered car has become the vehicle for workaday use, and that in future the open touring car will be reserved for purely pleasure purposes in fine weather. Most manufacturers, however, now include in their standard productions a sunshine saloon that may be used in either open or closed form. This is a type that has been very popular during the past year, and is likely to become more so now that greater attention is being paid to rendering them perfectly waterproof, a requirement that has not in the past been entirely met in all cases.

Hours and Prices of Admission

Finally, it may be mentioned that the show will be open from 10 a.m. to 10 p.m., and that the charge for admission on the opening day, Thursday next, will be 10s., 2s. 6d. on the two Fridays and Saturdays, and 5s. on all the other days. Although the fact that more space is available on this occasion may reduce the congestion of the stands and aisles experienced in past years, those intending to visit Olympia may be reminded that the crowds do not usually arrive until the afternoons and evenings, so that the mornings provide the best opportunity for a close examination of the exhibits.

Next week it is proposed to review the main features of the exhibition, and to deal briefly with some of the new models of cars especially suitable for medical motorists.

C. J. W.

Medical News.

THE nineteenth annual dinner of the Glasgow University Club of Manchester, Liverpool, and District will be held at the Midland Hotel, Manchester, on Thursday, November 13th, at 7 p.m. The chair will be taken by Dr. D. Sage Sutherland, and Professors T. K. Munro and C. H. Browning, along with Dr. G. H. Edington of Glasgow, have consented to be the guests of the club. Membership of the club is open to all graduates (male or female) of the university, and any who would like to attend the dinner and have not received details of it are requested to write to the honorary secretary, Dr. T. B. Riddall, 274, Dickenson Road, Longsight, Manchester.

THE new session of the Hunterian Society of London will commence on October 20th with a dinner meeting at Simpson's Restaurant, Birdcage Walk Court, Cheapside, at 7.15 p.m., when Professor A. W. Sheen will deliver his presidential address entitled "The school of health." At the meeting on November 17th, at 9 p.m., at Cutlers' Hall, Warwick Lane, a discussion on the place of the doctor in industry will be opened by Sir David Milne Watson, Mr. W. A. Appleton, Professor E. L. Collis, and Dr. Strickland Goodall. A dinner meeting will be held on December 15th, at 7.30 p.m., when a discussion on puerperal infection will be opened by Dr. Remington Hobbs and Mr. M. Oldershaw. The Hunterian Lecture, on the problem of rejuvenation, will be delivered by Dr. Arnold Lorand of Carlsbad at Apothecaries' Hall, Water Lane, on January 19th, at 9 p.m. The annual dinner of the society will take place at the May Fair Hotel on February 12th. Mr. A. E. Mortimer Woolf will deliver the Hunterian Oration on the surgical aspects of diverticulitis at Apothecaries' Hall on March 2nd, at 9 p.m. A discussion on the common cold will be opened by Dr. E. P. Poulton and Dr. Oliver Heath, at a dinner meeting, on March 30th, at 7.15 p.m. The annual general meeting of the society will be held at Simpson's Restaurant on April 30th.

THE annual general meeting of the West Kent Medico-Chirurgical Society is being held to-day, Friday, at 8.45 p.m., in the Miller General Hospital, Greenwich, and will be followed by the demonstration of clinical cases. The programme of the society during the coming session is as follows. On November 14th Drs. E. P. Cumberbatch and C. A. Robinson will speak on diathermy in gynaecology. The Purvis Oration will be delivered on December 12th by Mr. A. J. Walton, who has chosen for his subject the nerve-muscular obstructions of the intestinal tract. The first meeting of the new year will take the form of a clinical evening on January 9th. On February 13th Dr. F. M. R. Walshe will deal with the interpretation of some common symptoms of nervous disease, Dr. J. Forest Smith will discuss the treatment of goitre in general practice, on March 13th, and Mr. Edwin A. Lindsay will lecture on April 10th on the subject of common disabilities of the feet. The presidential address will follow on May 8th. The honorary secretary of the society is Dr. C. J. B. Buchan, 267, Baring Road, Grove Park, S.E. 12.

AT a meeting of the Society for the Study of Inebriety, to be held in the rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, W., on Tuesday, October 14th, at 4 p.m., Dr. Macdonald Critchley will read a paper on some forms of drug addiction.

THE opening meeting of the new session of the Royal Microscopical Society will be held in the Hastings Hall, B.M.A. House, Tavistock Square, W.C., on *Wednesday, October 15th*, at 5 p.m. The President and Mrs. R. Ruggles Gates will hold an informal reception, Mr. J. E. Barnard, F.R.S., will demonstrate by micro-projection some histological preparations from the society's collection, and Dr. G. M. Findlay will communicate some recent research on malarial parasites. The biological section will meet on Wednesday, November 5th.

A COURSE of fifteen post-graduate lectures and demonstrations on modern methods in the diagnosis and treatment of venereal diseases is being given by Lieut.-Colonel L. Taylor Burke at the V.D. Treatment Centre, Municipal Clinic, 155, Regent Road, Salford, on Thursdays, at 7 p.m. Lectures and demonstrations on congenital syphilis will be given at the clinic on October 16th, 23rd, and 30th, at 4 p.m.

THE first meeting of the British Institute of Radiology for the session 1930-31 will be held in the Reid Knox Memorial Hall of the Institute, 32, Welbeck Street, on October 16th, at 8.30 p.m., when papers will be read by Dr. J. F. Bromley on the use of negative paper, by Captain A. R. Wood on ultra-violet glasses, and by Dr. G. Simon on the use and technique of diathermy in the treatment of pneumonia. The first two papers will be accompanied by demonstrations. Members from the provinces will have an opportunity of visiting the radiological department of St. Mary's Hospital, Paddington, between 2 and 4 o'clock on the afternoon of the following day.

THREE Chadwick public lectures on rheumatism illustrated by lantern slides, epidiascope and films will be given in the Hastings Hall of the British Medical Association's House Tavistock Square W.C., on Thursdays, October 23rd and 30th and November 6th, at 5.15 p.m. The first lecture the significance of rheumatism in youth and middle age, will be by Dr Francis Bach with Sir William Collins in the chair the second on rheumatism in childhood will be by Dr Gerald Slot, with Sir Thomas Barlow, Bt. in the chair, and the third on the treatment of rheumatism will be by Dr Matthew B. Ray. Admission is free, without ticket.

A COURSE of lectures on 'Some newer therapeutic agents their pharmacological identification and tests, with some account of their uses in medicine' will be given by Dr J. H. Burn director Pharmacological Laboratories, Pharmaceutical Society of Great Britain in the lecture theatre, 17 Bloomsbury Square W.C.1, on Monday, October 13th, and succeeding Mondays at 5.30 p.m. Admission to the first lecture without ticket admission to subsequent lectures by ticket only. Tickets for the course may be obtained from the secretary of the society on the following terms: Members and student associates of the society gratis on application, registered apprentices or students 5s. other persons, 10s.

THE Child Study Society, London, has issued its programme of lectures to be delivered at the Royal Sanitary Institute, 90 Buckingham Palace Road, S.W. on Thursdays at 6 p.m. On October 23rd the first Cockburn Memorial Lecture entitled "The whole child" will be given by Dr James Kerr on November 13th Dr Arthur H. Norris chief inspector, Children's Branch Home Office will lecture on the methods of a modern reformatory and on December 4th Dr C. W. Kimmins will lecture on the changes in the child's attitude to life during the school period.

A GENERAL meeting of the Guild of St Luke St Cosmas, and St Damian will be held on Sunday, October 19th in the Cathedral Hall Archbishop's House Westminster S.W.1, immediately after the celebration of High Mass in Westminster Cathedral at 10.30 a.m. The annual report of the council contains a reference to a protest made in his pastoral letter by the Archbishop of Tuam against the advertising of quack remedies. Meetings of the council in London have been held regularly and have been fully attended similar meetings have also been arranged in Bath, Bristol Liverpool, Manchester Wolverhampton, Glasgow and Preston. These meetings have been reported in the *Catholic Medical Guardian*, which is the organ of the Guild. It is announced that a public meeting will be held in the Queen's Hall next February on the subject of Lourdes and modern medicine.

THE Fellowship of Medicine announces that the M.R.C.P. special course lectures for the week at the Medical Society, 11 Chandos Street, Cavendish Square, will be delivered on Monday October 13th, at 5 p.m., by Mr C. L. Gimblett (general medical ophthalmology, illustrated by epidiascope), and on Tuesday October 14th, at 8.30, by Dr L. S. T. Burrell (intrathoracic tumours). The fee for each lecture is 10s. 6d., payable at the lecture hall, and for the course of lectures (16) £6 6s. On Wednesday October 15th at 4.30 p.m. Mr G. G. Penman will give a demonstration entitled 'Fundi of general medical interest" at the Royal Westminster Ophthalmic Hospital this class is strictly limited. A course in diseases of the throat, nose and ear is in progress at the Central London Throat Nose and Ear Hospital, and will continue until October 31st, one in tropical diseases at the Tropical Hospital, will continue until October 24th. Fees are chargeable for these courses. From October 13th to 24th, at the Chelsea Hospital, there will be a special course in gynaecology occupying mornings and/or afternoons. The Fellowship of Medicine has arranged a series of lectures on recent advances in medicine and surgery. Dr G. E. Beaumont will give the opening lecture on Monday, October 13th at 4 p.m. entitled 'Recent advances in the medical treatment of some pulmonary emergencies.' The lecture will be delivered at the Medical Society and is open to the medical profession without fee or ticket. On October 13th at 3.30 p.m. will take place the first clinical demonstration of the winter session, this will be at the Miller Hospital Greenwich when Dr Harold Pritchard will demonstrate cases illustrating modern methods of diagnosis and treatment. On October 14th at 2 p.m. Mr C. P. G. Wakeley will give a clinical demonstration in the out-patient department at King's College Hospital. These demonstrations are free to medical practitioners. Particulars and syllabuses of all courses and tickets of admission may be obtained from the secretary of the Fellowship 1 Wimpole Street W.1.

THE International Red Cross Committee at Geneva announces that the international competition for the discovery of a detective reagent for the detection of mustard gas in the air which was started on July 1st 1929 is to close on December 31st. The prize offered is 10 000 Swiss francs (£400). The competition is the first step in a Red Cross campaign for the protection of civilians in the event of war. It is to be followed if funds permit by other international competitions to discover, among other things the best civilian gas mask and the best means of purifying the air in subterranean places in which civilians may take shelter during air raids. Full particulars of the competition may be obtained on application to the International Red Cross Committee, 1, Promenade du Pin, Geneva.

AT a meeting of the Society of Public Analysts on October 1st a paper by Mr G. W. Baker on scientific evidence relating to firearms, with special reference to a recent murder trial, was read and demonstrated by Mr G. H. Perry. Scientific methods of investigation were used in examining the bullet and cartridge case found on the scene of a murder in Jerusalem in August, 1929. By means of *x* ray photography it was established that a piece of a bullet found in one of the bodies was British ammunition and it was also proved that it had been fired from a rifle of the same calibre and rifling as that of the person accused. Further, it was conclusively shown by means of photomicrographs that the cartridge case found on the scene had been fired from his rifle for there were at least fourteen marks on the pin impression all of which were found on the firing pin of the rifle. The extractor mark was also a very characteristic feature. The court returned a verdict of guilty.

THE Society of German Medical Abstainers held its annual meeting at Dresden on September 2nd, under the presidency of Professor Emil Abderhalden, when it was decided to form a central library and information bureau relating to the alcohol problem.

A MEMORANDUM has been addressed by the Chief Medical Officer of the Ministry of Health to all medical officers in counties, county boroughs, and districts, directing their attention to the information contained in the Annual Statistical Review of the Registrar General for England and Wales, and referring to the reduced price at which sections of this publication will be available in future. The cost of the 'Tables Part I—Medical' will be 7s. 6d., and that of the text 2s. 6d. Synopses of the contents of these volumes with descriptions of regular and special features are appended to the memorandum to illustrate their usefulness for study and reference.

DR. R. M. HUTCHINSON LOW of Kensington has given £1,000 to the committee of the Wrexham and Denbighshire War Memorial Hospital to endow a bed in memory of his father and mother.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR British Medical Journal British Medical Association House, Tavistock Square, W.C.1***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager British Medical Association House Tavistock Square W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS as well as orders for copies of the *Journal* should be addressed to the Financial Secretary and Business Manager.

QUERIES AND ANSWERS.

EPHEDRINE

"M. M. M." has a patient a schoolmaster aged about 45 who has been taking ephedrine for asthma with beneficial results but has had to give it up for the following reason. Within an hour of taking a 1/2 gram tablet he finds a lithemy in passing urine and this continues for about twenty-four hours. Can anyone suggest a cause and a remedy?

ALUMINIUM COOKING VESSELS

"W S M writes A patient complained to me of an alteration in the taste of food cooked in aluminium vessels I always understood that no deleterious effects resulted from the use of aluminium as cooking utensils so long as no sodium bicarbonate was added to the food Is there any authoritative information available?

SACCHARUM

DR A R MCCLURE (Wellington, Salop) writes Every now and then one hears well authenticated tales of patients returning for a repetition of a mixture containing simply burnt sugar and water, because it is the only medicine that does them good This effect is rather hastily attributed purely to suggestion. But the effects of other and more costly elements exhibited in small amounts very finely divided, are due to properties of the substances themselves caramel consists partly of colloid carbon The consumption of saccharum in many practices is measured in gallons, there must exist, therefore, a body of evidence, based upon actual experience which, if available, might throw some light upon the indications if any for its specific employment The representatives of drug houses whom I have consulted personally believe that in many cases more caramel is actually used than would be necessary for colouring purposes

TREATMENT OF PRURITUS ANI

J M writes In the *Journal* of June 7th (p 1080) "Cerons" asks about the treatment of pruritus ani I suffered for many years in exactly the same way as "Cerons" I was quite free from any itching until I grew warm in bed, when it became intolerable Unguentum metallorum gave me almost immediate relief, applying it in the morning for three or four days entirely relieved me for about three weeks For about four years I was entirely free from the complaint, but three months ago it recurred in a very acute form I obtained immediate relief under the same treatment, and am now well I have never noticed this ointment mentioned as a treatment for the complaint I may add that I have treated many patients in the same way quite successfully

CHEIROPOMPHOLYX

DR HUGH WILLOUGHBY (Gravesend) writes In reply to "Symington's" inquiry I would suggest that he tries soaking his hands twice a day in water containing a teaspoonful of formalin to each pint of water, and allowing the hands to dry *without wiping* Alternatively he might try using an ointment composed of equal parts of salicylic and benzoic acids in lanoline (xv grains āā to 1 oz) I am myself a sufferer in hot weather, getting the infection on both my hands and feet, and the first remedy suggested never fails to alleviate the condition I come across many cases of this type of dermatitis in persons home from the Tropics, and suggest both methods of treatment with equal success I have observed that cold weather usually effects a cure without any active treatment, and patients from the Tropics have commented on the fact that recurrence is often noted on their reaching the Red Sea when returning to the East Like "Symington," I label these cases cheiropompholyx"

DR G M WILCOCKSON (Guildford) writes In June last I had a severe attack of this disease between each of the fingers of my right hand, first the irritation, and afterwards the smarting, were so bad that I could not sleep I frequently had to get out of bed and hold my hand in cold water As the condition did not attempt to clear up I went to the Skin Hospital in Fitzroy Square, where I saw Dr Cowen, who prescribed ung hyd. ammon dil gr x ad ʒj The condition was practically well after two weeks' treatment Dr Cowen said that $AgNO_3$ gr ij ad sp aetheris nitrosi ʒj applied to the papules when first they appeared, would often abort the attack I have found that so At present I have a recurrence between the index and middle fingers, a deep raw crack, which is yielding to the ointment

DR LEO SPIRA (London, N W 6) writes As a late sufferer from cheiropompholyx I sympathize with "Symington," and in answer to his query (October 4th, p 586) I refer him to my two articles, "Some skin manifestations and their relation to the disturbance of the gastro intestinal tract," *Irance British Medical Review*, October, 1928, and Chronic poisoning by an irritant contained in cooking utensils and tap water, *ibid* December, 1928 The method therein described effected a complete cure after many other kinds of treatment had been tried without success

INCOME TAX

Depreciation of Assistant's Motor Car

"W W B" uses his own car, but his principal pays tax and insurance, as well as petrol and other running costs Can he claim in respect of depreciation

*** Yes The allowance for "the diminished value by reason of wear and tear" was extended to the assessment of the profits or gains of an employment by Section 16 of the Finance Act 1925 The loss by wear and tear clearly falls on "W W B," and we can find no ground for refusing him the usual percentage deduction

Payment of Interest in Full

"PERPLEXED" is paying for the share of a retired partner in instalments, *plus* 5 per cent interest on the capital amount unpaid The recipient suggests that, as he is not liable to tax, the interest should be paid *without* deduction of tax

*** The legally correct course is for 'Perplexed' to deduct tax and for the retired partner to recover it from the authorities If, however, the latter can be satisfied that the tax is not ultimately due, we think that they will agree to the interest being paid in full and will make an allowance accordingly in assessing "Perplexed" But it is for the retired partner to agree to the necessary arrangement with the authorities

LETTERS NOTES, ETC.

ANHIDROSIS

A CORRESPONDENT writes to point out that the correct spelling of the word which means 'absence of perspiration" is, of course, *anhidrosis* The word "anhydrosis" would mean "absence of water"—from the Greek ἀ, the negative prefix, and ὕδωρ, water Anhidrosis'—or "anidrosis,' as it may be written—on the other hand, signifies "absence of sweat or perspiration" It is derived from the Greek ἀ and ἱδρώς, perspiration Hippocrates used the Greek word ἀνίδρωσις, a sweating, but also the words ἀνίδρως, 'without perspiration" and ἀνιδρωτί, an adverb meaning "sweatlessly Xenophon (in *Cyrus*) uses the word ἀνίδρωτος, "without having sweated"

GENERAL EDUCATION OF THE MEDICAL STUDENT

MR R S ILLINGWORTH (School of Medicine, Leeds) writes I have read with interest Professor Dean's article in the Educational Number of the *Journal* (September 7th) about the general education of the medical student I myself decided on my career at the age of 14, after taking my matriculation, and advisedly continued with classics, instead of changing over to the science side of the school I entered the University fully prepared for a year's really hard work in making up lost ground, but I soon discovered that less work was necessary for the year's chemistry, physics, and biology than for the higher certificate and county major scholarship, and I can say with confidence that the change over from classics to science offers no great difficulty At Leeds, at least the course starts with the very elements of the subjects, and the average student should have no trouble in keeping up with the work Of course, it is a little disconcerting to feel in October that one's knowledge of the required subjects is *nil* and to think that by June one is expected to have reached approximately higher school certificate standard But the novelty of the subjects makes them interesting, and I can truthfully say that I thoroughly enjoyed my first year in medicine My head master always said that classics teach one how to learn I believe him But I doubt whether it could truthfully be said that any other subject teaches one such an extremely important thing, and it is for this reason that classics provide such an excellent foundation for the study of medicine Anyone at the matriculation stage who had medical inclinations, and who was undecided whether to turn over to the science side, I should strongly advise to carry on with classics, to learn something about English literature, about Greek and Latin verse—especially Homer and Virgil, about ancient history and anthropology, about French and German, all of which subjects are taken in the "sixth classical" of a good school No, let no more be said about the handicaps a classical man has to face when he starts medicine, it may act as a deterrent to many

NECROPSIES AND THE GENERAL PRACTITIONER

"A C D" (Devon) writes The arguments of Dr Gibson and others who agree with him, while quite true, are, I think, beside the point The question is—How can the cause of death be most accurately ascertained? Does the average general practitioner in rural districts get sufficient experience in post-mortem examinations to give an opinion of much value except in obvious cases? And, if not, what is the remedy? Coroner's inquests are not held in order to help the doctor keep up his knowledge of pathology But, if he is worth his salt, he will attend the necropsy for that purpose, and to help the expert

SURGICAL THEATRE LIGHTING

A NEW hospital operating table lighting unit is being exhibited at present by Messrs Holophane, Ltd, Elverton Street, Vincent Square, S W 1 It consists of a special reflector, lamp, and lens in a frame, which is suspended from the ceiling, the apparatus is devised to ensure that the maximum beam of light shall strike the centre of the operation area A simply manipulated mechanism permits the position of the light to be varied, so as to suit different surgical conditions

MEDICAL GOLF

THE first meeting of the Sussex Medical (B M A) Golfing Society was held on Sunday, September 28th, on the links of the Brighton and Hove Golf Club This society has been formed to promote friendly games among members of the medical profession resident in Sussex, and for this competition a prize was given by the captain, Colonel P Dee The results were

First J H Twiston Davies 2 down, bracketed second J M Holmes and H G Downer 3 down

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 49, 50 51 52 53 54, 55, 58 and 59 of our advertisement columns, and advertisements as to partnerships, assistantships and locumtenencies at pages 56 and 57

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page *171*

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

322. Prognosis and Medical Treatment of Ulcerative Colitis

P Bayer (*Journ Med Assoc of South Africa*, July 26th, 1930 p 407) has investigated 20 cases of ulcerative colitis and analysed them from the standpoint of prognosis and treatment No patients suffering from colitis of specific (for example bacillary) origin or secondary to constitutional disease such as chronic nephritis were included A review of the author's cases yielded no indication of any definite etiological factor Most of the cases were of the severe type and there was a mortality of 25 per cent but two-thirds of the patients were either cured or definitely improved These indications of the seriousness of the disease are in accord with statistics obtained by other workers for similar series of cases Twelve of the patients were submitted to appendicostomy, two-thirds of them being either benefited or cured In several instances this operation marked definitely the turning point towards recovery The author considers that medical treatment should be given a thorough trial in every case The patient is kept in bed and septic foci if discovered are treated Vitamins fats and fruit are added to the usual lactofarinaceous diet but raw fruit and green vegetables are not given Pulv ipecac. co in 5-grain doses may be administered after every motion Rectal medication was followed by the best results when albargin tannic acid, and weak flavine or permanganate solutions were used for the lavage which was administered in the knee elbow position It was found that these and various specific measures such as the employment of serums and vaccines were equally ineffective in acute fulminating cases and in chronic cases with repeated acute exacerbations for these patients appendicostomy or occasionally caecostomy was performed When surgical intervention was decided upon an operation was arranged without delay A primary blood transfusion gave good results in some patients

323 Typhoid Fever due to Ice-cream

J Durich (*Pract Med de Barcelona* June, 1930 p 512) records an outbreak of 287 cases of typhoid fever, with 18 deaths which occurred between July 20th and October 30th 1928, at Santa Margarita Balearic Islands, which has a population of about 4,000 inhabitants 149 were females and 138 males The ages ranged from under 1 year to over 75 The source of the outbreak appeared to be the consumption of ice cream which had probably been infected by the water used in its preparation or by a carrier In a large proportion of cases—certainly over 50—the consumption of the ice-cream was immediately followed by manifestations of gastro-enteritis, the enteric symptoms developing later Oral administration of vaccine was tried in 403 persons of whom 51 had consumed the contaminated ice-cream of these 6 contracted typhoid fever Of the remaining 352, 189 had been exposed to infection by close contact with the typhoid patients, and of these 7 (of whom 2 had received insufficient doses) contracted typhoid With a few exceptions the attacks among the inoculated were mild and there were no deaths On the other hand of 261 non inoculated persons who partook of the infected ice cream 170 contracted the disease and 18 died

324 Auscultation of the Arteries of the Neck

A. Landau and J Held (*Arch des Mal du Caur* August 1930 p 497) believe that auscultation of the common carotid and subclavian arteries in certain cases of aortic disease may supply information which is not gained by auscultation at the usual areas The examination is made immediately internal or external to the sternal origin of the sterno-mastoid muscle and just below the junction of the inner and middle thirds of the clavicle In normal individuals by light pressure of the stethoscope a systolic sound is heard followed by one corresponding to closure of the aortic valves The sounds are loudest in the right carotid fainter in the left and weaker still in the subclavian arteries In aortic incompetence a systolic murmur is well heard at these areas but the diastolic sound is very faint when there is stenosis of the aortic orifice the systolic sound is prolonged while the second is imperceptible as at the aortic area Auscultation at the precordium in aortic atheroma and in hypertension may be hampered by poor conduction through the chest wall but at the right carotid may be heard a systolic murmur or a loud and ringing second sound Similar signs are discoverable in syphilitic aortitis generally, but in a certain proportion of these cases they are best heard in the vessels on the left side of the neck, particularly in the left subclavian artery In the latter group palpation of the arteries and comparative blood pressure measurements sometimes show a reduction in force of the pulsations on the left side In these cases there is probably a narrowing of the orifice of the left subclavian artery Occasionally this sign is heard in the left subclavian artery but no disparity in the blood pressure measurements on the two sides is found, in these circumstances there is probably a lesion of the arch of the aorta in the neighbourhood of the orifice of the left subclavian artery

325 Prognosis in Pleurisy with Effusion.

F W Gaarde (*Journ Amer Med Assoc* July 26th, 1930 p 243) considers that the frequency with which pleural adhesions are found at necropsies and accidentally by radiological examinations would indicate that the milder form of pleurisy is common Undoubtedly patients often recover without the diagnosis of pleurisy having been made The etiology is generally considered to be tuberculous and although the condition is termed primary pleurisy it may be metastatic from a tuberculous process which cannot be found or perhaps from an old quiescent lesion A study of 126 cases of idiopathic pleurisy was made for the purpose of ascertaining if possible, the factors which influence prognosis The disease was found to occur more frequently in the second and third decades although the incidence of death was not out of proportion to that in other decades Tables are given of the incidence by decades of the state of health and length of life after onset and of the results of guinea pig inoculations It would seem that if a patient survives the original acute attack of pleurisy with effusion there is a good chance of complete recovery If he survives the first three years and particularly the first five his chances of complete recovery are excellent. Positive results of guinea pig inoculations render the prognosis more grave Gaarde thinks it is clear that idiopathic pleurisy with effusion should be considered as tuberculous and that the patient should have his life rigidly regulated for some months be kept at rest, and be treated by the methods applicable in tuberculosis If this is done and the patient is not permitted to return to work as soon as he has recovered from the acute symptoms, the prognosis will be much more favourable

Surgery

328 Air Embolism during Laminectomy

S P Fedopoff and A S Wischnewsky (*Centralbl f Chir* August 23rd 1930 p 2038) have on three occasions observed air embolism during laminectomies while cutting through the vertebral arch the operation being in each case between the third and fifth dorsal vertebrae They state that a vein is seen to bleed bubbles of air are observed a thrill murmur is heard and cyanosis and dyspnoea follow Two patients died almost immediately, in the third case the vein was plugged at once with muscle and the patient lived The danger zone is said to be on the right side, where the intervertebral veins collecting blood from the anterior vertebral plexus join the intercostal veins and run into the vena azygos In the intervertebral foramina at the base of the vertebral arch there is little tendency for the veins to collapse since they are held by periosteum The negative pressure in the upper part of the vena azygos is especially high and in the region of the third to fifth dorsal vertebrae the path to the superior vena cava is broad and direct The authors suggest that special care should be taken in operations in this area while cutting through the vertebral arch The periosteum and with it the veins should first be stripped from the bone At the earliest sign of venous bleeding a piece of muscle should at once be used to plug the damaged vessel Local anaesthesia is advised, so that the patient may if necessary be instructed to stop breathing until the danger is over.

327 Parathyroid Excess and Deficiency

O Lanz (*Deut Zeit f Chir* July 1930 p 378) describes a moribund case of post operative tetany in which relief followed the ingestion of raw parathyroid glands from horses and sheep cure was obtained by the implantation in the muscles of the abdominal wall of a fresh parathyroid gland removed from another patient by thyroidectomy Lanz also reports a bed ridden case of fibrocystic disease of some years

duration with an ununited spontaneous fracture of the femur, from which, at Professor Snapper's suggestion, he removed a nodule from the thyroid gland, this was found to be an adenoma of the parathyroid The blood calcium percentage, which had been as high as 21 6 mg , fell in the course of twenty four hours to 14 5, after five days to 8 5, and in three weeks to 6 6 mg Though the local symptoms of pain and tenderness rapidly diminished after the operation the patient soon developed marked restlessness and irritability He was treated by subcutaneous injections of parathormone and intravenous injections of a calcium preparation until the blood calcium had been raised to 9 04 mg per cent , and the calcium excreted daily in the urine, which was 400 mg before the operation, had been reduced to one tenth of that amount Six months after the operation the fracture had united and the patient was able to get about on sticks, six months later *x* ray examination showed that the bones had become re calcified, and the case was not only clinically but radiographically definitely cured

328 Tuberculosis of the Tongue

R D'Aunoy and J W Miller (*Journ Amer Med Assoc , July 12th, 1930, p 97*) believe that lingual tuberculosis is rare, only 334 cases having been recorded before March, 1929 The lesion is usually associated with tuberculosis in other organs, generally in the lungs, primary lingual tuberculosis is probably very unusual Diagnosis may be difficult, the appearance may resemble gumma or epithelioma, but these may be excluded by histological examination and by a negative Wassermann reaction The authors report three cases, all the patients being men, aged 54, 36, and 51 years respectively, and having signs of pulmonary tuberculosis In two cases extensive excision of the ulcer resulted in apparent cure of the lingual lesion The prognosis in these cases is said to be bad, although three authors state that even in fairly advanced cases favourable response may follow tuberculin therapy

329 Painful Abdominal Scars

F W Bancroft (*Arch of Surg* , August, 1930, p 289) considers that the post operative pain and soreness in abdominal scars may be due to neuromas rather than to post operative adhesions or neurasthenia Four cases are reported in which the symptoms were due to neuroma or traumatic neuritis of the lower thoracic nerves The diagnosis was based on the following facts in three cases the injection of procaine hydrochloride into the fascia of the right rectus muscle relieved the pain for a time, while in three cases symptoms were relieved by excision of all the scar tissue Post-operative pain in abdominal scars can be compared with the peripheral pain in amputation stumps, which has been shown by microscopical examination to be due to neuroma The author considers that incision through the right rectus muscle should never be made, since a high percentage of hernias, weak wounds, and nerve injuries follow this incision In each of the four cases reported, pain in the scar had followed an operation in which a right rectus incision had been made Kaumeier's incision is advocated, the McBurney and low Pfannenstiel incisions are described as being well planned to avoid nerve trauma Ligaturing a blood vessel with its accompanying nerve, or the mass tying of vessels in the vicinity of nerves, should be avoided.

Therapeutics.

330 Treatment of Sea-sickness

P Vogt Möller (*Ugeskrift for Laeger*, July 17th, 1930, p 700) has studied the problem of sea sickness during twenty four crossings of the Atlantic in 1928 and 1929 He found that more than three quarters of his patients were women, whose sea sickness was more severe and protracted, as a rule, than that of the male patients The best purely mechanical device proved to be keeping them as near to the centre of the ship as possible, since at this point the movements of the ship were less than anywhere else The drugs tested were morphine, veronal and its derivatives, bromine salts, adrenaline, cocaine (used as a local anaesthetic for the stomach), strychnine, camphor caffeine, chloretone, benzyl benzoate, sodium nitrite, and atropine Neither the severity nor the duration of the sea sickness was influenced by any of the drugs in this list when they were swallowed, even atropine by the mouth proved quite ineffective, though it had some effect when given by subcutaneous injection The combination found most successful was a 0 1 per cent solution of atropine sulphate with a 0 1 per cent solution of scopolamine bromide given subcutaneously or in suppositories The dose of the atropine was from 0 5 to 1 25 mg , and that of the scopolamine from 0 25 to 0 5 mg , no ill effects other than slight dryness of the mouth, easily relieved by water, were observed Even when the temperature of the air was tropical there were no discomforts from interference with the secretion of sweat Although the results of this treatment were described as amazingly good, the effects of a single injection or suppository were not necessarily immediate, but after three or four injections, distributed over a couple of days, most of the patients could leave their berths and felt well. In severe cases the average duration of the sea sickness was reduced by three days by this treatment In many cases only one or two injections or suppositories were necessary in order to restore the patients to a complete sense of well being, even though the sea remained rough.

331 Treatment of Essential Hypertension.

R S Palmer (*New England Journ Med* , July 31st, 1930, p 208) reviews the recent literature on the treatment of essential hypertension, and enumerates the various measures that have been recommended in this affection He suggests that the following criteria may be useful in estimating the hypotensive action of any given remedy Each observation shall consist of at least ten successive determinations of the systolic and diastolic pressures at one minute intervals, the same type of instrument being used at each observation with the patient in the same position This investigation should be carried out, when possible, on ambulatory patients, exposed to the usual daily occurrences Two, or preferably more, weekly observations should be made before starting treatment The securing of preliminary rest is optional A fall in the average of the ten readings at successive visits should be demonstrable after a period allowed for the full effect of the treatment, and this effect should be maintained at two or more further observations The patient should remain under treatment for four to six weeks, when it should be stopped and a rise in blood pressure be shown after ample time has been allowed for the effect of the procedure to have abated Finally, a second hypotensive effect of the treatment should again be demonstrable In the absence of specific measures, the guiding principles in the treatment of hypertension are diminution to a minimum of nervous strain and responsibility, reduction of over weight in the obese, and special care in the early recognition of the disease in those with a cardiovascular family history, with an attempt to control its progress Certain patients will respond to a well ordered hygienic regimen of limited responsibility, daily rest periods, and mild exercise This should be instituted in all cases, with the addition of mild sedatives such as potassium sulphocyanate, or the administration of antispasmodic drugs such as the nitrites or theobromine compounds Balneotherapy may be tried in an institution or regular warm baths in the home of the patient

332. Actinotherapy in Whooping-cough

G Barraud (*Journ de Méd de Paris*, July 2nd, 1930, p 577) states that though some foreign observers maintain that ultra violet rays do not produce any satisfactory result in whooping cough, French actinotherapeutists are of the opinion that they may be of value, not by shortening the duration of the disease, but rendering the attack very mild and avoiding complications and sequelae The technique is as follows The irradiation is concentrated on the thorax at a distance of 80 cm , and the treatment should last ten minutes The applications should be made every other day, and the duration should be increased ten minutes each time, an erythema dose being used In 33 cases so treated 27 recovered rapidly, 3 showed some improvement, and 3 no change If recovery does not ensue after the sixth application there is no need to continue the treatment, but in severe cases as many as twelve applications may be employed to improve the general condition, especially if there is a tendency to tuberculosis The conditions for success are, first, that the treatment should be started early, secondly, that the doses should be sufficiently strong , and, thirdly, that the application should be applied at frequent intervals (every two days)

333 Treatment of Tetanus

A. E Paterson (*Med Journ of Australia*, June 28th, 1930, p 832) records his observations on the treatment of 26 children, aged from 4 to 11 years, and suffering from tetanus, 19 recovered and 7 died On admission 100,000 units of serum were injected intravenously under an anaesthetic and 40,000 intramuscularly The intravenous injection was repeated in twelve hours' time, and then at intervals of twenty four hours The intramuscular injections were given every four hours, the amount being gradually lessened As convalescence approached, the interval between each injection was lengthened The total number of units given in the cases which recovered ranged from 120,000 to 1,970,000

Disease in Childhood

334 An Infantile Asthmatic Syndrome.

H JUMON (*Presse Med*, August 23rd, 1930 p 1138) discusses the syndrome of asthma skin eruptions and hepatic deficiency appearing in infancy and childhood up to the age of 6 These signs are first recognizable in the early months of life they frequently though not invariably coexist develop by a series of bouts are generally found in cases of what the author terms a "neuro-arthritic diathesis, and tend to spontaneous cure at the age of 8 to 10 or at puberty Cure may, however, be hastened by treatment Infantile asthma occurring typically in the age period up to 6 years, is a paroxysmal dyspnœa catarrhal in nature There may be attacks of capillary bronchitis with pyrexia the prognosis is good recovery being by crisis or lysis in 24 to 48 hours Mild cases take the form of an apyrexial bronchitis In older children the asthma is generally of the adult type appearing precociously, being spasmodic in character, it has no association with cutaneous or hepatic manifestations and no tendency to a natural cure, being often due to some discoverable cause Pseudo-asthmas are due to local conditions in the nose or mediastinum or to general causes such as disease of the heart or kidney The association with asthma is definite in cases of pruritus with secondary eczema or lichen and of Hebra's prurigo of the French type, it is doubtful in the true prurigo of Hebra and rare in simple prurigo or strophulus —a transitional form between simple prurigo and urticaria. Hepatic manifestations may take the form of cyclic vomiting with acetonæmia More characteristically there is in association with the asthma and the skin lesion slight pyrexia, anorexia nausea coated tongue constipation headaches fatigue weakness, and acetonuria In general these children are thin and pale, with a dry skin

335. Treatment of Constipation in Children

R M SMITH and H E GALLUP (*New England Journ Med*, April 24th, 1930 p 802) discuss constipation in children and its treatment by a residue-free diet They find that the condition may be overcome in a considerable proportion of cases by prescribing foods with high roughage and residue content as for example the cellulose from vegetables and the husks of fruits and cereals, combined with mineral oil and a laxative or agar agar. Many children, however, especially with long standing constipation and pronounced symptoms of pain vomiting faulty posture and malnutrition do not respond to such a line of treatment In these the constipation is due to the disturbed function of the distended colon this condition tends to become worse upon a cellulose residue diet which increases the bulk of material retained as hard masses or adherent to the mucous membrane In such cases the aim is to reduce the faecal residue *to a minimum* and to empty the colon completely by excluding all roughage from the diet Vegetables cereals, and fruit must be strained through a fine sieve and coarse bread avoided By administering mineral oil in half to one teaspoonful doses after each meal three times a day the passage of the faecal mass within the colon is facilitated, and two to four teaspoonfuls of castor oil at bedtime once a week may assist During the first few weeks simple enemata, given cautiously so as not to distend the colon may be necessary Improvement begins in most cases within a few weeks and the enemata should be abandoned as soon as possible, the intervals between the doses of castor oil lengthened, and the amount of mineral oil gradually reduced When the cure is accomplished the condition of the colon should be ascertained by a barium enema followed by another after a full diet has been continued for some time in order to determine whether the improvement is maintained

336. Latent Scurvy in School Children

DEFICIENCY of vitamins in the diet may entail unsuspected dangers, and F HAHN (*Med Welt*, May 10th 1930 p 664) commends Ludolf Brauer for defining the initial symptoms of threatening scurvy (1) easy fatigue and distaste for work, (2) loss of appetite, or, on the other hand the appetite persisting even after meals (3) painful shins or joints (4) bleeding from the gums and the scurvy rash (rare) and (5) petechiæ (often misunderstood and treated with sulphur) and other haemorrhages. Hahn states that pains in the shins and bleeding gums are frequently seen in children's clinics from March to May After examining 300 family food consumption lists from Hamburg he concludes that many families consume an inadequate quantity of antiscorbutic foods in spring unless they have gardens Deficiency of vitamins lowers the power of resisting infection and he attributes to this cause the fact that influenza occurs more frequently in spring than in autumn This vitamin deficiency in spring also explains why the monthly Hamburg death rate highest in the cold weather of December has a second maximum hardly lower, in March while this second maximum is certainly less noticeable in rural districts Some German hospitals and sanatoriums have increased the vitamin content in their dietaries and find that they can now more quickly cure their spring patients who are slow as a class to recover To avoid vitamin deficiency fresh fruit is a desideratum, and children should take cod liver oil daily during the four months of winter He doubts whether all advertised preparations of vitamins are effective and also harmless one such preparation which is extensively advertised in Germany is thought to cause arterio-sclerosis, even if given in quite small doses. If the water soluble vitamin C is deficient scurvy occurs, but if the fat soluble vitamin A is lacking xerophthalmia then appears being shown in the early stage by redness and itching of the conjunctivæ This eye condition is said to be common in the schools about April and is apt to be mistakenly ascribed to ophthalmic strain *consequent on the children preparing for* their examinations

Obstetrics and Gynaecology

337 Low Cervical Caesarean Section.

TRACING the development of low Caesarean section from its inception in 1805 C W SEWALL (*New England Journ Med*, August 21st 1930, p 356) states that the present operation while technically more difficult to perform than the classical one is simple and direct It is relatively much safer, diminishing the maternal risk *approximately* to 1 per cent. as compared with 4 per cent for other methods and because of the lessened risks it possesses a broader field of application than high operations There are many advantages in this method. In contracted pelves it is possible to allow a more thorough trial labour with a subsequent abdominal operation if necessary Vaginal examination is not so fraught with risk as in the case of *intraperitoneal operations* Placenta praevia, uterine rupture pelvic or uterine tumours eclampsia and accidental placental detachment are easily and successfully handled by the low route Local instead of general anæsthesia can be readily employed The operative field is practically in the pelvis and lower abdomen and the uterine wound is extraperitoneal The cervix being relatively non contractile and less vascular than the uterine body healing is more rapid and complete, there is less haemorrhage and less danger of uterine rupture in subsequent pregnancies The only disadvantage of this operation is the apparently greater number of neo-natal intracranial haemorrhages resulting from it These haemorrhages seem to occur more often in cases where there has been no labour and Sewall suggests that a certain amount of labour may be beneficial Some useful points in operative technique are given, and the following suggestions are made When abdominal delivery is contemplated a few hours of carefully observed labour may be beneficial an incision large enough to allow easy passage of the head should be made Using the hand as a chute with compression of the fundus from above brings about delivery of the head quickly and with a minimum of trauma The routine injection into the newly born child of a large dose of maternal whole blood is prophylactic as regards the prevention of haemorrhage

338. Virilism in Ovarian Tumour

G A WAGNER (*Deut med Woch*, July 4th 1930, p 1120) reviews the literature on 32 cases of ovarian tumour associated with virilism including two observed by himself. The patient is most commonly a young woman who until the onset of symptoms has shown normal feminine characteristics, and may have borne children Menstrual abnormalities are the rule, irregularities appear at first and there is often sudden and complete cessation About the same time the hair takes on the masculine distribution there being a well marked beard the skin becomes coarser and darker the subcutaneous fat less and acne of the type often seen in male adolescents may develop temporarily Later the face takes on an ugly masculine appearance the larynx alters and the voice deepens sometimes to the bass compass the figure becomes more thick-set and the muscles stronger and more prominent *The skeleton however is unaltered.* The breasts diminish in size but the external genitals remain of female type except in cases of long duration where there may be hypertrophy of the clitoris The uterus and unaffected ovary are mostly normal The sexual emotion usually remains female in character though changes have been recorded in some cases. After the removal of an ovarian tumour at an operation the return to normal femininity is most striking menstruation usually commences *within four*

to six weeks and remains regular, while the other symptoms of virilism gradually disappear The tumour found in all carefully recorded cases is of very unusual type, and has been named "androblastoma" by Meyer, who believes that it consists primarily of undifferentiated germ cells developing towards the masculine type The appearances of the tumour vary considerably they may be sarcoma like and diffuse, or more highly differentiated, showing tubular areas and epithelium Some almost belong to the group of tubular (testicular) adenomata Different grades of differentiation may be found in the same tumour Though histologically the tumour is obviously malignant, it is remarkable in most cases for its relatively innocent character, only a few cases of cachexia, metastasis or recurrence having been recorded In one case the symptoms of virilism disappeared after the operation, but returned one and a half years later owing to a recurrence of the tumour It is remarkable that virilism is the rule with this type of growth, though it rarely occurs in cases of testicular adenoma The author discusses other causes of virilism, and remarks that such extreme degrees of the opposite condition—feminism in the male—are unknown.

339 Primary Carcinoma of the Fallopian Tubes

R E WATKINS and W M WILSON (*Surg., Gynecol and Obstet*, July, 1930, p 125) report a case of primary carcinoma of the Fallopian tube The disease is rare, only about 200 cases having been reported in the literature A woman, aged 50, seven months before coming under observation complained of a blood stained watery vaginal discharge, it had commenced suddenly and was gradually becoming more profuse, being accompanied by sacral backache and slight soreness in the lower right quadrant of the abdomen Examination disclosed a firm, tender, moderately movable mass posterior to, and to the right of, the uterus No sign of inflammation or free fluid was found at operation, and the uterus and the left adnexa were normal The right tube was enlarged in its distal half to form an oval tumour about 5 by 6 cm in diameter, when this was opened after removal, a haemorrhagic, friable, papillomatous growth was found to occupy the whole lumen No pelvic lymphatic glands were felt, but the entire uterus and left adnexa were removed After a fortnight's normal convalescence she was discharged, returning at regular intervals for deep *x* ray therapy, and five months later she appeared to be well From other reported cases it would appear that the age incidence is that of cancer generally The etiology is unknown, but many authors consider that a commonly associated chronic salpingitis is a predisposing factor With the exception of a watery, occasionally blood stained, vaginal discharge there are no characteristic signs or symptoms, and a correct diagnosis has only once been made prior to operation Although in the case reported the ovary was not involved, and there were no evidences of retroperitoneal lymph gland metastases, the opposite is frequently the case The microscopical appearance is that of a papillary alveolar type of tumour, commencing as a malignant hyperplastic change in the cylindrical epithelium of the tube The case reported demonstrates the value of immediate section of extirpated pelvic tumours

Pathology.

340 Action of Morphine on the Liver

I PAVEL, ST M MILCOU, and I RADVAN (*Paris Méd*, August 9th, 1930, p 125) have been investigating the action of morphine on the biliary secretion, using dogs with a biliary fistula, the common bile duct having been ligatured and divided At the time of experiment the dogs had been fasting for eighteen to twenty hours, they were then given food, and fifteen to thirty minutes later 1 cg (in one case 2 cg) of morphine hydrochloride was injected hypodermically There was noted a definite inhibition of the production of bile, the quantity secreted ranging from two fifths to one eighth of the normal This inhibition, first apparent ten to fifteen minutes after the injection, increased progressively until, often, at the end of two or three hours, secretion stopped The normal rate of bile flow was re established slowly There was a relative increase and an absolute decrease in the amount of bile pigments and, probably, of bile salts The action of morphine on the detoxicating function of the liver was also studied The detoxicating power of the liver was measured by the amount of retention of rose bengal Six dogs which had been kept fasting for twelve to twenty four hours received an injection of 1 to 2 cg of morphine, thirty to ninety minutes later 1 5 mg of rose bengal for each kilo of body weight were injected It was found that 1 cg of morphine caused an increase in the amount retained normally, while 2 cg doubled the amount retained A further investigation related to the action of morphine on urobilinuria, Piersol, Rothman and Hetenyi having expressed the view that urobilinuria afforded the best evidence of hep[illegible] The quantity of urobilin present was [illegible] after morphine administration The present authors submit evidence indicating that morphine acts directly on the liver cell They call attention to two points of clinical importance (1) fifteen minutes after an injection of morphine 33 per cent of the drug may be recovered from the liver, the other organs containing only 1 to 3 per cent, and (2) fatal results have followed the injection of morphine in cases of established hepatic disease

341 Estimation of the Minute-Volume of the Circulation in Man

THE minute volume of the circulation can be determined from a formula based on the calculation of oxygen used and of the CO_2 output per minute, the percentage of oxygen and CO_2 in the arterial blood, and the percentage in the mixed venous blood Up to the present the values for mixed venous blood have had to be calculated indirectly from analysis of the alveolar air O KLEIN (*Munch med Woch*, August 1st, 1930, p 1311) points out that since Forssmann has shown that it is possible in the living subject to pass a long catheter up the median basilic vein into the right auricle of the heart, estimation of the gaseous tension of mixed venous blood can now be carried out directly on samples collected from the heart in this way A No 6 ureteric catheter is used, lubricated with fine sterile oil A small opening in the vein is made, the arm abducted, and the catheter gently inserted with practically no force The position of the catheter is confirmed radiographically In straightforward cases five to seven minutes suffices for the whole procedure In the course of eighteen such experiments no ill effects were observed during or after the passage of the catheter In several cases estimations of the minute volume of the circulation were made, and the results agree closely with those found by other authors In about 40 per cent of cases, however, it is not possible to reach the heart, since the catheter tends to travel up side channels It is claimed that the method can be employed in the case of patients with circulatory disease, in some of whom samples of alveolar air would be impossible to obtain

342 Estimation of Urine Alkalinity in Gastric Ulcer

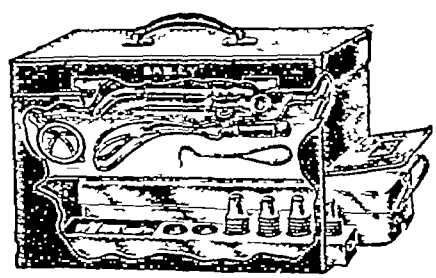
L ANFANGER (*Deut med Woch*, May 16th, 1930, p 823) has repeated the work of Balint, who stated that after administration of a certain amount of alkali by the mouth the alkalinization of the urine was delayed in cases of definite ulcer of the stomach, this was attributed to the overacidity of the tissues, which Balint regarded as the chief factor in the pathogenicity of ulcer of the stomach and duodenum. Sahm has shown, by estimating the hydrogen ion concentration of the urine, that after the daily administration of 10 to 20 grams of alkali to cases in which there was no ulcer of the stomach, the urine became alkaline on the third to the eighth day, but that this was delayed to the ninth to the sixteenth day in cases where gastric ulcer was present Anfanger has estimated the acidity of the urine in twelve patients with healthy stomachs and obtained alkalinization of the urine on the third to the eighth day In five cases with definite ulceration of the stomach there was a delay to the tenth to the fourteenth day, but in nine other cases with definite ulcer this delay did not occur It is concluded that the estimation of the urine alkalinity after the administration of alkali for gastric disease is not of diagnostic value for ulcer of the stomach

343 Etiology of General Paralysis

S NICOLAU and P GUIRAUD (*C R Soc de biologie*, July 11th, 1930, p 963) have attempted to transmit syphilis to rabbits by inoculating them with brain material from eight fatal cases of general paralysis All these cases were typical, giving a positive colloidal benzoin and Wassermann reaction in the spinal fluid, and a lymphocytosis being present The brain was removed as soon as possible after death, and portions of the parietal or frontal cortex were excised Suspensions in saline solution from five cases were inoculated subdurally into rabbits, two being employed in each instance The animals were *observed for two months and showed* no evidence of disease From the other three cases rabbits were inoculated beneath the skin of the scrotum on both sides, and in another set of rabbits both testicles were so treated About two and a half months later the rabbits were killed, and the popliteal glands were used for the sub-scrotal inoculation of fresh rabbits, these animals were killed after two months and their popliteal glands used for a fresh passage The results obtained were absolutely negative, and agree in this respect with those of previous workers

de KUYPER'S

HOLLANDS



Distilled from genuine malt liquor with the Juniper berry added The advantage gained by distilling the berry with the spirit is the production of a preparation of Oleum Juniperi, mellow and free from irritating properties

Oleum Juniperi is official in the British Pharmacopœia, and is described as carminative, anti-spasmodic, and a stimulating diuretic.

In this form, therefore, the oil of Juniper can be safely taken with regularity

Distilled by the same family for 233 years

W. H. BAILEY & SON

S C 1360

S C 1360—Bailey's large size Surgeons Midwifery Case, made in best Cowhide fitted with Slide Tray to take six 1-oz bottles in metal cases and Chloroform Drop Bottle, in separate compartment at side of Sterilizer

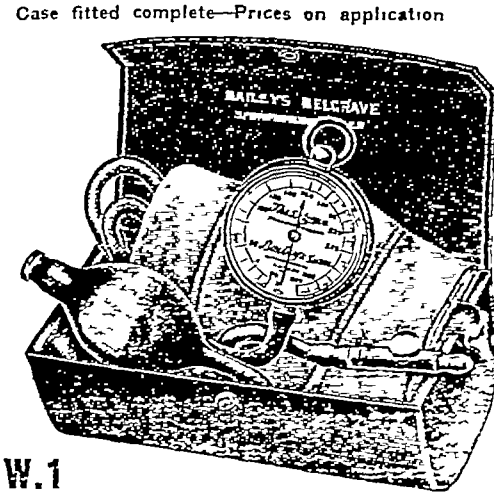
Size 17 × 10 × 7 £3 15 0

Ditto fitted with best nickel plated stamped-out seamless 10-in Sterilizer (with lamp and tray) £5 15 0

Case fitted complete—Prices on application

BAILEY'S "BELGRAVE" SPHYGMOMANOMETER

BRITISH MADE THROUGHOUT



A thoroughly reliable Instrument and guaranteed accurate Extremely sensitive Light and portable

The Tubes may remain attached to the dial as the interior of the case allows sufficient room to prevent kinking

An essential apparatus for the General Practitioner

Price £2 15 0

Post free United Kingdom Abroad 2 6 extra.

HOW EVERYONE CAN LEARN A FOREIGN LANGUAGE

PELMAN INSTITUTE'S REMARKABLE DISCOVERY

Can you read Spanish?
No
Do you know any German?
No
Here are two books one printed in Spanish, the other in German
Yes
Can you read them?
Of course not
Well try and see

An Hour Later

Miraculous! I can read and understand every word

* * * *

The above conversation is typical of the experiences of the thousands of men and women who are now learning French, German, Spanish, and Italian by the new Pelman method

A Business Man, for example, visits the Languages Department of the famous Pelman Institute He is a very poor linguist He knows a little French, but not much He doesn't know a single word of Spanish German, or Italian Yet when handed a book printed entirely in Spanish and another printed in German (neither containing a word of English), he is able to understand every word

Needless to say such a visitor is immensely impressed and at once enrols for the Pelman Course in the particular language in which he is interested

Still more numerous are those who write for particulars to the Institute and receive in return a free copy of a book describing the method in detail They, too decide to enrol and soon become enthusiastic admirers of the new method

This method enables you to learn French in French, German in German, Italian in Italian, and Spanish in Spanish, thus avoiding all translation from one language into another

It enables you to *think* in the particular language you are learning

It enables you to dispense with the labour of memorising by heart (parrot-fashion) long vocabularies of foreign words You learn the words you need by actually using them, so that they stay in your mind without effort

It enables you to write and talk in a foreign tongue to read foreign newspapers and magazines and to enjoy the masterpieces of French German Italian and Spanish literature many of which have never been translated and all of which especially in the case of Poetry lose much of their charm in an English version

There are no classes to attend The new method enables you to learn your own language in your spare time, and in from one-third to one half the usual period

General Sir Aylmer Haldane GCMG, KCB, DSO, writes "The Pelman method is the best way of learning French without a teacher

Here are a few typical examples of letters received from readers who have adopted this new method of learning French, Spanish, Italian, and German —

It would have taken me as many years to learn by any ordinary method as much (French) as I have learnt in months by yours (P 145)

I have only been learning German for four months now I can not only read it but also speak it well (GM 146)

'I have obtained a remunerative post in the City solely on the merits of my Italian I was absolutely ignorant of the language before I began your Course eight months ago (H 121)

I have recently returned from Spain where I have been doing Consular work With only the knowledge of Spanish gained from your Course I was able within a month to tackle any sort of correspondence and conversation (SC 279)

In fact, everyone who has followed it is delighted with the ease, simplicity, interesting nature, and masterly character of the new Pelman method

This new method of learning languages is explained in a little book entitled "The Gift of Tongues" There are four editions of this book, one for each language The first explains the Pelman method of learning French, the second explains the Pelman method of learning German, the third explains the Pelman method of learning Spanish, the fourth explains the Pelman method of learning Italian

(1) Courses in Afrikaans and Urdu

You can have a free copy of any one of these by writing for it to-day to the Pelman Institute, 74, Languages House, Bloomsbury Street, London, W C 1

State which book you want and a copy will be sent you by return, gratis and post free Write or call for it to-day

What is your opinion about underwear?

DO YOU not think that woollen underwear is undoubtedly the healthiest?

Besides its absorbency, Wolsey keeps the temperature even against sudden excesses of heating and cooling

Nowadays, too, Wolsey is made in so many weights and styles that it can be as light and airy as could be wished, and yet it is warm.

Wolsey pure wool underwear has a reputation of 30 years to recommend it. You can advise it with confidence

KEEPING EXPENSES DOWN AND APPEARANCES UP

Unquestionably one of life's greatest problems is keeping expenses down and appearances up, especially as most people take us at our face value.

Keith Bradbury's object is to help you keep appearances up and expenses down, by offering to provide you with West-End clothing on terms from £1 per month to suit your convenience. (Cash or quarterly accounts available if preferred)

All garments are cut and fashioned to satisfy the exacting needs of men accustomed to the master touch of the West-End tailor, and every customer is waited upon by one of the Principals

A FREE VALET SERVICE is also provided to preserve the smart appearance of garments after purchase, so you see we take a sincere interest in our customers' good appearance.

An interesting catalogue, patterns or particulars of our special financial arrangements will be gladly sent on request, or better still, may we have the pleasure of a call

DOCTORS CHINA TEA

WHY IT IS PRESCRIBED FOR GASTRIC PATIENTS

When ordinary tea is out of the question it is essential that only really good China should be drunk The Doctors China Tea has won the enthusiastic approval of practitioners simply because it is a perfect blend of a good China leaf with all excess tannin eliminated It can therefore be prescribed for invalids and dyspeptics with safety—it has no ill after effects

Priced at 3/ and 3/8 per lb A super quality at 4/2 per lb

STANIFORM
Regd. BRAND Trade Mark

METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns scalds etc

DUSTING POWDER
For application where a greasy substance is counter indicated

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis

LOTION
A panacea for Mosquito and other insect bites Most effective for all purposes where Tr Iodine is employed Does not stain the skin and there is no sting

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use

Supplies may be obtained through the Wholesale Druggists Druggist Sundries men or Dental Supply Companies

What the Profession says

The following are some recent unsolicited testimonials reported to the Manufacturers by Medical Men

I continue to get every satisfaction from 'Staniform' in the case of carbuncles boil, whitlows and all kinds of infected wounds

In a case of acute eczema on leg the skin was quite normal within one week after starting application of Staniform Ointment

Festering wound on left heel when first seen was about the size of a shilling with good deal of pus Foot much swollen—dressed with Staniform Ointment healed splendidly in four days

Similar testimony has been received from a large number of medical men when Staniform has been used for the treatment of Burns, Wounds, and Skin Ailments

STANIFORM is used in Leading Hospitals

STANIFORM over a wide field of clinical experience has exhibited positive curative properties Combining the well known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing

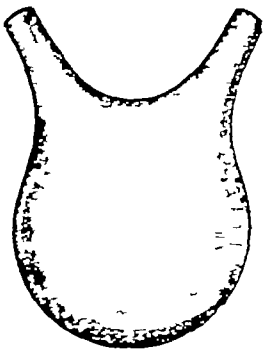
INVALID DIET

The high Vitamin B content of Marmite, together with its digestibility and appetising flavour, make it a most useful item in the diet of invalids and convalescents Marmite is a concentrated extract of Yeast. It is often the only form in which yeast can be tolerated by the patient

Medical Practitioners are invited to write for free sample to Marmite Limited Walsingham House Seething Lane E C 3

MARMITE



MINCHIN'S CHESTPIECES

(REGISTERED)

For Single and Binaural Stethoscopes

Being set at right angles to those in general use afford the following advantages Time is saved as little undressing is necessary Bed patients can be examined without disturbance The heart can be examined whilst patient lies face down with the result that sounds are much more distinct This also applies to the Fœtal Heart Children can be more readily examined by this Chestpiece than by the older patterns as it is not necessary to stand in front of them Also made with attachment for use with Sphygmometer

To be obtained from all Surgical Instrument Makers

For Restful Ease or Surgical Positions—

Simmons Hospital Beds are instantly adaptable

A turn of the crank adjusts the Simmons Bed into any desirable position For convalescents this means maximum repose, for it dispels the necessity of constantly rearranging pillows

The strong construction of Simmons Beds and their hygienic qualities make them invaluable to all Hospitals and Institutions

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

1. It is individually fitted to suit the case for young middle-aged or old
2. It is simple and true-to-tone and leaves the hands free
3. It removes strain thus relieving head noises, giving inconspicuous hearing
4. It conveys sounds from varying ranges and angles.
5. It is entirely different uncopyable and carries a guarantee and service system
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation music talkies, wireless, home office public work and sports.

FREE HOME TESTS

arranged for Doctors and Patients

Medical Prescriptions made up to the minutest detail

"ARDENTE" STETHOSCOPE

Mr P H Dent makes a Stethoscope specially for members of the Medical profession suffering from deafness Many are in use and excellent results are reported on the latest as evidenced by the interest shown at the last B.M.A. Meeting
